IMPORTANT NOTICE

This report was prepared exclusively for Newfoundland and Labrador Hydro by Resource Innovations Inc. and Amec Foster Wheeler Environment & Infrastructure, a Division of Amec Foster Wheeler Americas Limited (Amec Foster Wheeler). The quality of information, conclusions and estimates contained herein is consistent with the level of effort involved in the above noted companies' services and based on: i) information available at the time of preparation, ii) data supplied by outside sources and iii) the assumptions, conditions and qualifications set forth in this report. This report is intended to be used by Newfoundland and Labrador Hydro only, subject to the terms and conditions of its contract with Amec Foster Wheeler. Any other use of, or reliance on, this report by any third party is at that party's sole risk.

EXECUTIVE SUMMARY

Newfoundland and Labrador Hydro (Hydro) is proposing to develop a transmission line (TL 267) across southeastern Newfoundland, from Bay d'Espoir to the Western Avalon Peninsula (the Project). The development of the proposed TL 267 will involve the clearing and control of vegetation along the right of way and other ground disturbance which, given the linear nature and geographic extent of the Project, will cross through a variety of vegetation communities and habitats.

The purpose of this Ecological Land Classification (ELC) Study has been to identify, categorize and map local ecosystems, including vegetation types and communities and associated habitats, within and adjacent to the proposed Project Area (40 m wide right of way) and a larger, surrounding Study Area (1 km wide). This 2015 study has focused primarily on the section of TL 267 between Bay d'Espoir and Come By Chance, a summary of the main results of which is provided below:

2015 ELC Habitat Type	40 m Wide Right of Way (ha)	1 km Wide Study Area (ha)
Softwood Forest	108.66	2,509.49
Hardwood Forest	8.75	249.96
Mixedwood Forest	67.37	1,503.73
Softwood Scrub	66.10	1,527.65
Hardwood Scrub	0.74	22.21
Herbaceous	4.24	197.25
Barren	85.94	2,259.48
Shrub	37.67	895.67
Wetland	143.78	3,807.00
Anthropogenic / Other	37.37	1,085.51
Total	560.62	14,057.95

The remaining section of the proposed TL 267 between Come By Chance and the Western Avalon Terminal Station near Chapel Arm was the subject of a previous ELC Study (Stantec 2010), which included the classification of 184.82 and 4,591.37 ha of habitat within the above described right of way and Study Area, respectively, based on 11 defined habitat types. For completeness, the relevant results of that study are also summarized and mapped in this report.

The associated Map Atlas presents the detailed results of the ELC at the 1:15,000 scale. The resulting GIS system contains this information at a scale of 1:5,000, and can be further analyzed and queried in detail as required.

The information provided through this ELC Study is intended to support the Project's Environmental Assessment (EA) registration and review, and will be used in on-going Project planning and design as well as in the eventual permitting and construction / mitigation planning for the Project.

1.0 INTRODUCTION

Newfoundland Labrador Hydro (Hydro) owns and operates an extensive electrical generation and transmission system on the Island of Newfoundland, which includes a 613 megawatt (MW) hydroelectric generation station at Bay d'Espoir in the south-central portion of the Island, as well as several transmission lines that extend between it and other electrical infrastructure and load centres across the Island. This includes two existing transmission lines that run from that facility to Sunnyside which were constructed in the late 1960s, as well as a transmission system that extends between Sunnyside and Chapel Arm.

The proposed development project that is the subject of this study includes the construction and operation of a new 230 kilovolt (kV) transmission line that will be approximately 188 km long and connect the existing Bay d'Espoir and Western Avalon Terminal Stations (hereinafter also referred to as the "Project" or "TL 267"). The proposed TL 267 will parallel existing transmission line infrastructure from Bay d'Espoir to Come by Chance (TL 202 and TL 206) and further parallels TL 203 from Come by Chance to the Western Avalon substation in Chapel Arm (Figure 1). Upgrades to existing infrastructure at the Bay d'Espoir and Western Avalon terminal stations will also be completed as part of this Project. The existing transmission lines (TL 202, 203 and 206) were cleared and constructed within the boundaries of the easement granted to Hydro by Government at the time of their development, as will the proposed TL 267.

Given that this new transmission line and associated infrastructure will follow entirely along existing transmission lines and other infrastructure in the region, the Project is expected to have few if any environmental issues associated with it. Hydro is, however, committed to ensuring that Project construction and operations are conducted in an environmentally responsible and acceptable manner, in full compliance with associated environmental regulations and permits, as well as the company's own environmental policies, plans and standards.

The Proponent has therefore planned and completed an environmental study program in relation to the proposed Project, in order to obtain and compile information on key aspects of the existing biophysical and socioeconomic environments within and near the Project area. The information provided through this study program is intended to support the Project's Environmental Assessment (EA) registration and review, and will be used in on-going Project planning and design, as well as in the eventual permitting and construction / mitigation planning for the Project.

This *Ecological Land Classification (ELC) Study* comprises one component of that environmental study program.

Figure 1 - The Proposed Bay d'Espoir to Western Avalon Transmission Line (TL 267)

1.1 Study Rationale and Purpose

The development of the proposed transmission system will involve the clearing and control of vegetation along the right of way and other ground disturbance which, given the linear nature and geographic extent of the Project, will cross through a variety of vegetation communities and habitats.

The purpose of this ELC Study has therefore been to identify, categorize and map local ecosystems, including vegetation types and communities and associated habitats, within and adjacent to the proposed Project Area.

The ELC is a core environmental study that has formed the basis for several other study components and analyses, as well as associated environmental management and mitigation planning for the Project.

2.0 APPROACH AND METHODS

The following sections describe the general approach used in the completion of the ELC Study, including the Study Area, data sources and the overall methods used to compile and present the resulting environmental information.

2.1 Ecological Land Classification: An Overview

The fundamental basis for the delineation of ecological units is to identify and describe their main ecological composition and the linkages between their various components, including landforms, soils, water and vegetation (Marshall et al. 1999), as well as the occurrence, distribution and relative abundance of these components and characteristics within the geographic area of interest. The particular scale at which landscapes are defined and evaluated can also be variable, depending on the specific objectives and goals of the associated analysis and its geographic and ecological context.

In Canada, a hierarchical system has been developed to map and analyze the presence and characteristics of ecosystems at various geographic scales. This provides a relatively consistent spatial context within which ecosystems can be classified and described. This framework is comprised of a nested hierarchy that describes regional ecological units at various scales, in which larger ecological units encompass progressively smaller ones.

The *ecozone* is at the top of the ecological framework hierarchy in Canada, and defines the ecological mosaic of Canada on a sub-continental scale. Each ecozone represents an area of the earth's surface representative of large and very generalized ecological units that are characterized by interactive and adjusting abiotic and biotic factors (Marshall et al. 1999). Canada is divided into 15 ecozones, of which only one will be crossed by the proposed Project.

The Boreal Shield Ecozone includes parts of six Canadian provinces and covers more than 1.8 million square kilometers, including almost 20 percent of Canada's land mass and 10 percent of its surface water (Wiken 1986). The topography of this ecozone is comprised of rolling uplands that form poorly drained depressions blanketed with lakes, ponds, and wetlands. With a mostly continental climate, the region experiences long, cold winters with short warm summers with abundant precipitation. A short growing season coupled with acidic soils reduces vegetation productivity in this ecozone, although most of the area is forested primarily by coniferous species intermixed with hardwoods and wetlands. Lichens and shrubs are also common on areas of exposed rock (Wiken 1986).

Ecoregions are smaller ecological units that have distinctive, recurring patterns of vegetation and soil development, which are determined and controlled by local climate and geography. Also called "natural regions," ecoregions differ from each other in their combinations of plant communities, landscapes, geology, and other features (NL PNAD 2015). The proposed transmission line will pass through three of the Ecoregions that have been identified on the Island of Newfoundland (Damman 1983; NL DNR 2015), including (primarily) the large Maritime Barrens Ecoregion (79 percent of the transmission line's linear distance), along with smaller

portions of the Central Newfoundland Forest Ecoregion (18 percent) and Western Newfoundland Forest Ecoregion (three percent) at its ends. Within the Maritime Barrens Ecoregion, the proposed right of way occurs primarily within the Central Barrens Subregion with a smaller portion on the Avalon Peninsula falling within the Southeastern Subregion. The section of the transmission line within the Central Newfoundland Ecoregion crosses two Subregions, Twillick Steady near Bay d'Espoir and Northcentral near the Isthmus of the Avalon Peninsula (Figure 2).

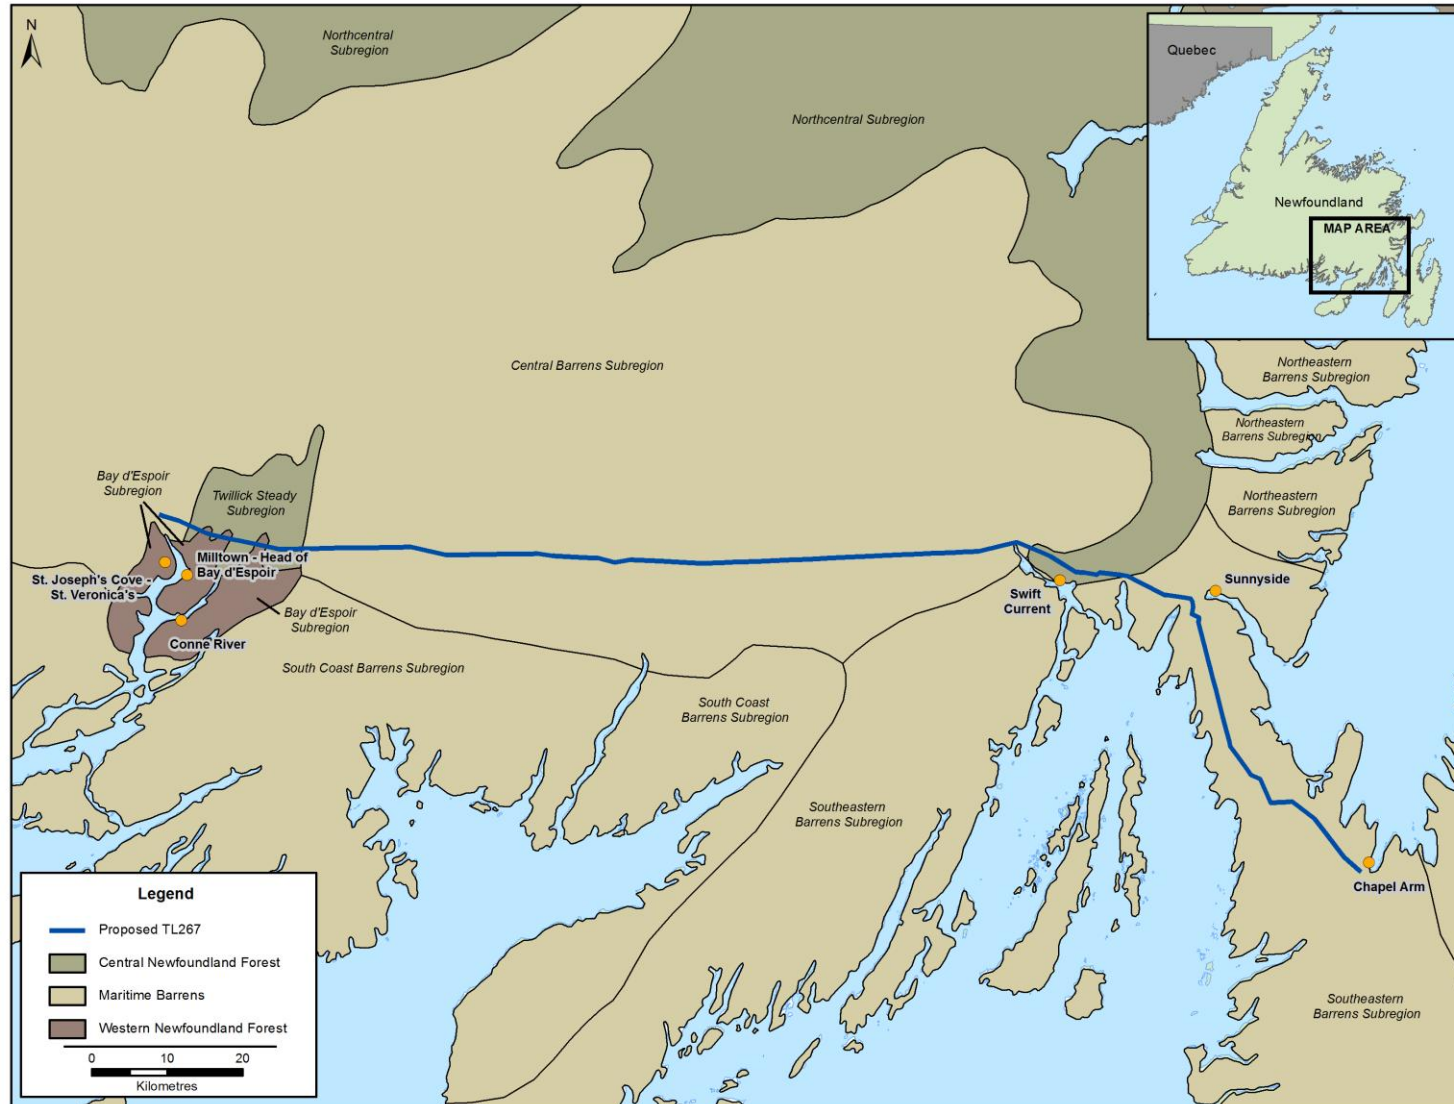

The Maritime Barrens Ecoregion is characterized by cool summers with frequent fog and strong winds. Winters are relatively mild with intermittent snow cover. Consequently, this ecoregion is dominated by open heathland and peat bog interspersed with patches of stunted balsam fir (*Abies balsamea*), black spruce (*Picea mariana*) and eastern larch (*Larix laricina*). Heath plants are primarily *Kalmia angustifolia* on protected slopes and *Empetrum nigrum* or *E. easmesii* on windswept ridges and headlands (Meades 1990; NL DNR 2015).

The Central Newfoundland Ecoregion has a more continental climate than the Maritime Barrens area, with cooler winter and higher summer temperatures. Forest fires have historically been more frequent in this ecoregion and have led to a replacement of balsam fir-*hyloconium* forest types over many areas. However, upland areas within the Twillick Steady Subregion remain dominated by balsam fir forest. Ground cover in the Northcentral Subregion is primarily dwarf shrub heath (*K. angustifolia*) with interspersed stands of balsam fir and black spruce. Topography in both subregions is less than 300 m above sea level and the topography is rugged and undulating (Meades 1990; NL DNR 2015).

The Western Newfoundland Forest Ecoregion (Bay d'Espoir Subregion) is characterized by a humid climate with a relatively longer frost-free period. Higher humidity reduces the prevalence of fire as a disturbance mechanism and favours the growth of *dryopteris*-balsam fir forest rather than black spruce as the dominant tree. Rich soils also support the growth of yellow birch (*Betula alleghaniensis*) in sheltered valleys of this subregion (Meades 1990; NL DNR 2015).

The proposed Project will also cross through a portion of the existing boundaries of the Bay du Nord Wilderness Reserve (2,895 km²), which encompasses a vast landscape of ponds, rivers, barrens, bogs and fens, forests, and thickets in south-central Newfoundland.

Figure 2 - Ecoregions and Subregions in Newfoundland Crossed by the Proposed Project

2.2 Study Areas

The proposed Project will include construction and operation of a new electrical transmission system along existing transmission lines and roadways in south-central and eastern Newfoundland for a total distance of approximately 188 km. In completing this ELC Study, the associated analysis has focused upon a number of geographic scales, including:

Project Area or Transmission Line Right of Way: A specific routing has been selected for the transmission line, which will involve a cleared right of way approximately 40 m wide.

Study Area: The larger (1 km wide) Study Area extends 500 m on either side of the centre line of the identified right of way for the proposed TL 267, as described above. This surrounding area is considered in order to provide relevant, regional context for the analysis, as well as address the potential for Project-related activities to occur outside the 40 m wide transmission line routing itself.

Through the ELC analysis, a detailed overview and summary of the vegetation cover types within each of these areas is provided in the next Chapter and in the data tables included as Appendix A, with this information being shown graphically in the ELC Map Atlas included as Appendix B.

This study focuses primarily on ELC habitat types along the proposed TL 267 as far east as where the proposed transmission line meets the existing TL 203, near Come By Chance. The remaining section of the TL 267 right of way, between Come By Chance and the Western Avalon Terminal Station near Chapel Arm, was the focus of a similar ELC several years ago (Stantec 2010). For completeness and reference, the ELC habitats and associated areas identified within that section of the Study Area are summarized in Chapter 3 of this report and the associated Appendices. That previous study (Stantec 2010) should be consulted for further details on its ELC methodologies and findings.

2.3 Analytical and Mapping Methods

2.3.1 Spatial Imagery and Ortho-photography Data and Analysis

High resolution colour imagery acquired by Hydro was used as the basis for the ELC analysis and mapping. This imagery (flown by a fixed wing aircraft with an attached high resolution camera) consists of 3,504 individual images covering the Project and Study Areas extending from Bay d'Espoir to Sunnyside at a resolution of 15 cm per pixel. This imagery and its IMU (Inertial Measurement Unit) was utilized and incorporated within a developed geographic information system (GIS) workflow. In addition, a LiDAR (Light Detection and Ranging) dataset that was captured concurrently with the imagery was also acquired and used in the analysis. These LiDAR data were provided in LAS format and were then classified and processed into a compatible format to be utilized for feature extraction by the interpreters (see below). The Study Team produced several surface models to assist in feature identification and validation, including surface models containing ground elevation data, vegetation classification based on height as well as classified slope, aspect and hillshade rasters. Processed LiDAR datasets have been analyzed for the full extent of the Study Area and the 40 m wide transmission line right of way at a raster resolution of not less than 1 m per pixel.

These two data sources were combined in a GIS for analysis and eventual mapping. Data delineation, capture and analysis was performed within an RDBMS (Relational Database Management System) and SQL (Structured Query Language) Server utilizing Stereo Analyst (digital stereo viewing software) product extensions to enable the visualization and capture of true stereo features while enhancing feature integrity during both the capture and data cleaning process. This enabled interpreters to accurately assess ground and/or cover type over the extent of the Study Area. Factors such as topographical slope and vegetation height are readily apparent when using stereo mapping methods such as those described above.

Using the above described spatial imagery and topographical information, a stereo analysis (using stereo imaging software to view and collect true three dimensional values) was completed. Utilizing ArcGIS and industry standard spatial data protocols, preliminary mapping was conducted based on the initial classification list developed. Initial feature digitization was completed using 3D polyline features. Once linework had been completed, these lines were then transformed to polygon Z features (namely, polygons that store 3D data).

The ELC mapping was completed using polygons delineated during softcopy air photo interpretation. Delineation and classification both generally occurred at a scale of between 1:2,000 and 1:5,000. While efforts were made to maintain a scale close to 1:5,000 for the analysis, finer scales were necessary at times to ensure proper classification and/or feature extraction. The mapping was supported by the interpretation of LiDAR datasets to provide detailed slope, aspect and elevation models. ELC mapping completed for the entire Study Area followed 1 hectare minimum standards.

The proposed 40 m wide transmission line right of way and the adjacent 1 km wide Study Area was segmented (using stereo imagery and any additional pertinent data sources available) along its width by using the defining characteristics on which the previously mentioned classification system was founded. The interpreter physically assessed each of the resulting polygons in stereo (3D) and assigned an ecological land class based on local characteristics such as the presence / absence of vegetation communities, tree species, moisture (for wetlands, bogs, and riparian thickets), and other key and defining characteristics.

Through the support of the Study Team's geospatial analysts, ELC data validation was completed utilizing advanced geoprocessing tools to further analyze data derived by the interpreter to enhance output mapping products and data integrity. All spatial datasets developed were validated against input LAS datasets (industry-standard binary spatial data format used to store and distribute point cloud LiDAR datasets). LiDAR data was then classified, allowing the interpreter to delineate, classify and attribute feature classes using several 3D inputs for stereo data with the highest possible integrity.

2.3.2 Vegetation Typing and Mapping

Experienced digital aerial photography interpreters used the ArcGIS and Stereo Analyst combination to classify all ELC polygons within the previously mentioned spatial extents. Each individual polygon was visually assessed to determine its characteristics. Similar vegetation, wetland and anthropogenic features were grouped together while areas exhibiting characteristics significantly different were separated as necessary and classed appropriately. The environment in which interpreters delineated and classified allowed for multi-interpreter classification, through which the data were continuously

evaluated and validated for data integrity using spatial databases. Geodatabases were developed using domain and coded value tables which enable the interpreters to classify the data based on pre-defined variables, eliminating user error based on feature types within the database. This also allows for further refinement, classification and additions to the geodatabase. Each domain also contains coded value tables which further break down each domain value. For example, the Form – Bog domain contains nine possible bog types found within the Canadian Wetland Classification System. Each coded value table includes every feature type found within that classification system for the entire extent of the Study Area.

Areas determined to fit the wetland ecotype were intensely scrutinized and classified as per the Canadian Wetland Classification System guidelines, down to the individual wetland form or sub-form if applicable and where possible. It is important to note here that in some cases it appeared that certain areas within the landscape had experienced damage from ATV use and other factors, which did lead to some uncertainty surrounding the specific classification of for example individual wetlands as key features were obscured, changed, or unable to be determined. In addition, some determining factors for proper wetland classification (such as peat type and depth) may be somewhat difficult to determine from an ocular assessment alone.

ELC analysis and reporting was completed to produce statistical information of mapping units and ecological land classes, and a quantitative analysis of the amount and area in each class identified within the transmission line right of way and larger Study Area.

3.0 RESULTS

The following sections provide an overview of the key results and outcomes of the ELC Study, including the associated vegetation mapping results for the 40 m wide right of way and the 1 km wide surrounding Study Area.

3.1 ELC Habitat Types / Classes

The ELC analysis for this Project resulted in 10 primary ecotypes being identified, delineated and mapped for the TL 267 Study Area. Two of the primary ecotypes have a number of sub-ecotypes which have been identified during the analysis. Each ecotype is listed and described below, and were defined based on the dominant vegetation cover and the interpreter's field experience and familiarity with such ecotypes in Newfoundland and Labrador and elsewhere.

3.1.1 Softwood Forest

The softwood forest class describes areas of forested land which have:

- A combined total crown closure of greater than or equal to 20 percent.
- A species composition greater than or equal to 70 percent softwood.
- A site capability enabling the production of a merchantable forest at an average rotation age.

3.1.2 Hardwood Forest

The hardwood forest class describes areas of forested land which have:

- A combined total crown closure of greater than or equal to 20 percent.
- A species composition greater than or equal to 70 percent hardwood.
- A site capability enabling the production of a merchantable forest at an average rotation age.

3.1.3 Mixedwood Forest

The mixedwood forest class describes areas of forested land which have:

- A combined total crown closure of greater than or equal to 20 percent.
- A species composition where the dominant species is less than 70 percent hardwood or softwood.
- A site capability enabling the production of a merchantable forest at an average rotation age.

3.1.4 Softwood Scrub

The softwood scrub class describes treed areas which have:

- A combined total crown closure of greater than or equal to 20 percent.
- A species composition where the dominant species is greater than 50 percent softwood.
- A site capability which prevents the production of a merchantable forest at an average rotation age usually due to limiting environmental factors such as elevation, shallow soils, and/or nutrient deficient sites.

3.1.5 Hardwood Scrub

The hardwood scrub class describes treed areas which have:

- A combined total crown closure of greater than or equal to 20 percent.
- A species composition where the dominant species is greater than 50 percent hardwood.
- A site capability which prevents the production of a merchantable forest at an average rotation age usually due to limiting environmental factors such as elevation, shallow soils, and/or nutrient deficient sites.

3.1.6 Herbaceous

The herbaceous class describes areas dominated by herbaceous vegetation, which is defined as non-woody plants which die back at the end of a growing season.

3.1.7 Barren

The barren class describes areas which have:

- A combined total treed crown closure of less than 20 percent.
- Vegetation dominated by lichen and/or ericaceous plants.
- Substrates dominated by bedrock and/or thin layers of soil/organic matter over bedrock.

3.1.8 Shrub

The shrub class describes areas dominated by shrub vegetation, which is defined as small to medium sized woody plants (alder, willow, mountain maple, etc.).

3.1.9 Wetlands

The Canadian Wetland Classification System (National Wetlands Working Group 1997) describes a wetland as land that is saturated with water long enough to promote wetland or aquatic processes, as indicated by poorly drained soils, hydrophytic vegetation and various kinds of biological activity that are adapted to a wet environment.

As part of the ELC, wetlands have been identified and delineated and were classified down to the form and subform levels where possible and relevant, the detailed results of which are provided in a separate Wetlands Inventory and Classification Study Report (Amec Foster Wheeler 2015).

For the purposes of the ELC Report itself, identified wetlands are described and mapped as a single “wetlands” ELC type in the tables and mapping that follows.

3.1.10 Anthropogenic / Other

A number of non-vegetated ELC types were also identified and mapped through the ELC, which are collectively termed “Anthropogenic / Other”. The various sub-classes within this category are described below.

Water

The water class is described as any permanent water feature where the surface area was determined to be greater than 1 hectare in size.

Exposed Bedrock

The exposed bedrock class includes any site where vegetation is generally absent and exposed bedrock is dominant.

Transportation Routes

The transportation route class includes permanent road structures which appear to be passable through visual assessment.

Disturbed – Industrial

The disturbed – industrial class comprises any permanent and/or semi-permanent structures associated with industrial activities such as (but not limited to) power generating stations and associated facilities.

Disturbed – Residential

The disturbed – residential class includes any cleared areas dominated by dwellings and/or urbanized features such as municipalities, cabin developments, or others.

Disturbed – Farmland

The disturbed – farmland class includes human worked land areas where the assumed purpose was the creation and use of productive farmland.

Disturbed – Insect

The disturbed – insect class includes areas which appear to have been depleted by a previous insect outbreak(s) and do not currently meet the definition of either the softwood, hardwood or mixedwood forest class.

Disturbed – Cutover

The disturbed – cutover class includes areas which appeared to have been exploited by modern timber harvesting methods and do not currently meet the definition of either the softwood, hardwood or mixedwood forest class.

It is recognized that a portion of the Study Area associated with the existing transmission line rights of way (TL 202 and 206) is considered to be previously disturbed habitat. A large portion of this area has been defined as shrub, scrub, wetland and barren ecotypes, and is essentially void of forest habitat due to previous clearing (Appendix B). There are also sections of the existing transmission line rights of way that would not be considered disturbed, especially in areas where forest habitat was not the original ecotype (scrub, wetlands and barrens). This is seen where ecotypes outside of the existing rights of way are contiguous with those inside it (see map pages 14-20 in Appendix B, for example). Keeping in mind that while the existing transmission line rights of way were originally developed through anthropogenic influences, these now provide important functional habitat and movement corridors for various wildlife in the area. For this reason, the existing transmission line rights of way were not grouped with the above described “Anthropogenic / Other” ELC type (which include roads, trails, buildings and other cleared area) but rather were classified according to the relevant vegetated (non-anthropogenic) habitat types described earlier.

3.2 ELC Results Summary

Table 1 provides a summary of the results of the ELC vegetation analysis for both identified transmission line right of way (40 m wide) as well as the overall (1 km wide) Study Area. A more detailed breakdown for the Anthropogenic / Other ELC Type is provided in Table 2.

Table 1 - Summary of ELC Habitat Types (Areas and Proportions) - 2015 ELC Study

ELC Habitat Type	Area (ha)	Percent
TL 267 Right of Way (40 m wide)		
Softwood Forest	108.66	19.4%
Hardwood Forest	8.75	1.6%
Mixedwood Forest	67.37	12.0%
Softwood Scrub	66.10	11.8%
Hardwood Scrub	0.74	0.1%
Herbaceous	4.24	0.8%
Barren	85.94	15.3%
Shrub	37.67	6.7%
Wetland	143.78	25.6%
Anthropogenic / Other	37.37	6.7%
Total	560.62	100.0%
ELC Study Area (1 km wide)		
Softwood Forest	2,509.49	17.9%
Hardwood Forest	249.96	1.8%
Mixedwood Forest	1,503.73	10.7%
Softwood Scrub	1,527.65	10.9%
Hardwood Scrub	22.21	0.2%
Herbaceous	197.25	1.4%
Barren	2,259.48	16.1%
Shrub	895.67	6.4%
Wetland	3,807.00	27.1%
Anthropogenic / Other	1,085.51	7.7%
Total	14,057.95	100.0%

Table 2 - Summary of Anthropogenic / Other ELC Type (Areas and Proportions) - 2015 ELC Study

Anthropogenic / Other ELC Type (<i>Detailed Breakdown</i>)	Area (ha)	Percent
TL 267 Right of Way (40 m wide)		
Water	31.53	84.4%
Exposed Bedrock	1.36	3.6%
Transportation Routes	0.69	1.8%
Disturbed - Commercial	0.03	0.1%
Disturbed - Residential	0.00	0.0%
Disturbed - Farmland	1.45	3.9%
Disturbed - Insect	0.28	0.7%
Disturbed - Cutover	2.03	5.4%
Total	37.37	100.0%
ELC Study Area (1 km wide)		
Water	947.22	87.3%
Exposed Bedrock	25.97	2.4%
Transportation Routes	24.78	2.3%
Disturbed - Commercial	6.19	0.6%
Disturbed - Residential	2.61	0.2%
Disturbed - Farmland	11.78	1.1%
Disturbed - Insect	4.33	0.4%
Disturbed - Cutover	62.63	5.8%
Total	1,085.51	100.0%

To allow for optimal presentation and analysis of key environmental characteristics and features in the Project area and surrounding region, the ELC Study Area and proposed transmission line right of way have also been sub-divided into a series of 5 km long segments, with summary data being provided for each segment in Appendix A.

As noted previously, this study has focused primarily on ELC habitat types along the proposed TL 267 as far east as where the proposed transmission line meets the existing TL 203, near Come By Chance. The remaining segment of the TL 267 right of way, between Come By Chance and the Western Avalon Terminal Station near Chapel Arm, was the focus of a similar ELC several years ago (Stantec 2010). Table 3 provides a summary of the ELC results from that previous (Stantec 2010) ELC Study, based on the various habitat types that were defined and used in that analysis.

Table 3 - Summary of ELC Habitat Types (Areas and Proportions) – 2010 ELC Study

ELC Habitat Type	Area (ha)	Percent
TL 267 Right of Way (40 m wide)		
Conifer Forest	11.91	6.4%
Conifer Scrub	0.13	0.1%
Cutover	31.99	17.3%
Exposed Earth / Anthro / Cutblock	0	0.0%
Exposed-Earth / Anthro	8.71	4.7%
Kalmia Lichen / Heathland	10.16	5.5%
Mixedwood Forest	20.53	11.1%
Open Water	3.94	2.1%
Rocky Barrens	10.31	5.6%
Scrub / Heathland / Wetland Complex	87.04	47.1%
Wetland	0.08	0.0%
Total	184.82	100.0%
ELC Study Area (1 km wide)		
Conifer Forest	315.47	6.9%
Conifer Scrub	6.48	0.1%
Cutover	711.14	15.5%
Exposed Earth / Anthro / Cutblock	15.83	0.3%

Wetland	21.48	0.5%
Total	4,591.37	100.0%

The Map Atlas in Appendix B presents the detailed results of the ELC and associated mapping at the 1:15,000 scale. The associated GIS system contains this information at a scale of 1:5,000, and can be further analyzed and queried in detail as required.

4.0 SUMMARY AND CONCLUSION

The development of the proposed TL 267 will involve the clearing and control of vegetation along the right of way and other ground disturbance which, given the linear nature and geographic extent of the Project, will cross through a variety of vegetation communities and habitats.

The purpose of the ELC Study has been to identify, categorize and map local ecosystems, including vegetation types and communities and associated habitats, within and adjacent to the Project Area.

The information provided through this study is intended to support the Project's EA registration and review, and will be used in on-going Project planning and design as well as in the eventual permitting and construction / mitigation planning for the Project.
