

Estimation of Low Flows for the Province of Newfoundland and Labrador

A User's Guide

April 2017

**Government of Newfoundland and Labrador
Department of Municipal Affairs and Environment
Water Resources Management Division
St. John's, NL, Canada**

SUMMARY

The objective of this Guide is to provide users with a spreadsheet-based method of estimating 1-day and 7-day low stream flows with return period of 2, 10, 20, 50 and 100 years for the province of Newfoundland and Labrador. The spreadsheet can be used for both gauged and ungauged watersheds on either the the Island or for Labrador. The Guide also includes a walk-through example.

An overview of the study on which the estimation technique is based is also included.

1 INTRODUCTION

The characteristics and estimation of low flows are important for several water resources engineering and management applications such as estimating available water supply for municipal and industrial uses, determining the waste-water effluent dilution potential of a receiving stream, predicting the impact of stream diversions on the minimum flow requirements for spawning and migrating fish and generally, for environmental impact assessment studies.

An annual low flow condition is defined as a period during which the average streamflow is a minimum for the year. The duration of the low flow is usually measured in days and is expressed as an N-day low flow period. The magnitude of the low flow is expressed as the average daily flow (in m^3/s or L/s) over the continuous N-day period. For design purposes, low flows are usually expressed in terms of return periods in years. For example, a low flow with duration N-day, magnitude $x \text{ m}^3/\text{s}$ and return period T years is the average flow over N continuous days that one expects to be at or below $x \text{ m}^3/\text{s}$ on the average, at least once every T years. The particular combination of duration and return period chosen for characterizing a low flow is primarily a function of the intended water management or engineering application.

A M.Eng. thesis entitled “Low Flow Frequency Study for Newfoundland and Labrador”, completed in November 2012, describes the methodology and results of a frequency analysis of low flows at 60 (sixty) gauging stations on streams in the island of Newfoundland and 12 (twelve) gauging stations on streams in Labrador. A series of regression equations for estimating low flows of several durations and return periods at ungauged sections of streams were derived from the result of the analysis.

2 DATA ON GAUGED WATERSHEDS

The analysis of low flows was based on unregulated daily stream flows from 60 gauging stations in the island of Newfoundland and 12 gauging stations in Labrador. Figure 2.1 and 2.2 show the location of the gauging stations. Table 2.1 and 2.2 list these watersheds together with the locations of the gauges, the watersheds' drainage areas, and the record length available for each station. A database listing the physiographic parameters of the gauged watersheds with natural flows is presented in Table 2.3.

* Used only for the verification of results.
 DA= Drainage area; FA=fraction of forest area, SW= fraction of swamp area; FL= fraction of lake area; AB=fraction of barren area, L+S=fraction of lake and swamp area; ACLS= fraction of area controlled by lakes and swamps; LSF=lake and swamp factor, LAF=lake attenuation factor, DD=drainage density; SF= shape factor

Glossary of Table 2.3

DA = Drainage area

FA = Fraction of area controlled by lakes and swamps

SW = Fraction of swamp area

FL = Fraction of lake area

AB = Fraction of barren area

L+S = Fraction of lake and swamp area

ACLS = Fraction of area controlled by lake and swamps

LSF = Lake and swamp factor

LAF = Lake attenuation factor

DD =Drainage density

SF = Shape factor

3 REGIONAL LOW FLOW FREQUENCY ANALYSIS

Annual minimum low flows of 1-day and 7-day durations from the Environment Canada HYDAT database were used as input data into the Low Flow Frequency Analysis (LFA) computer program to obtain estimates of low flows with various return periods. The Province of Newfoundland and Labrador has been divided into two homogeneous regions – 1) Island of Newfoundland and 2) Labrador. Five candidate probability distributions, such as Generalized Logistic Distribution, Generalized Extreme Value Distribution, Lognormal Distribution, Pearson Type III Distribution, and Generalized Pareto Distribution have been examined to select a suitable probability distribution for the regions. Three parameter - lognormal distribution has been identified as the most suitable probability distribution for 1-day and 7-day LFA for both the regions. Frequency distribution of all sites in a homogeneous region is identical, except for site-specific physiographic factors. Using the physiographic factor, drainage area, a number of regression equations have been developed to determine the 1-day and 7-day low flows for gauged and ungauged watersheds in a homogeneous region for different return period. Mean annual minimum flow prediction equations and minimum low flow prediction equations for 1-day and 7-day are presented in Table 3.1 and 3.2.

Table 3.1 - Mean annual minimum flow prediction equations

| Region | Equation | R^2 |
|----------------------|--------------------------------|-------|
| Newfoundland (1-day) | $Q_{mean} = 0.0021 A^{1.1067}$ | 0.91 |
| Newfoundland (7-day) | $Q_{mean} = 0.0027 A^{1.0848}$ | 0.92 |
| Labrador (1-day) | $Q_{mean} = 0.0011 A^{1.1225}$ | 0.97 |
| Labrador (7-day) | $Q_{mean} = 0.0013 A^{1.1075}$ | 0.97 |

Table 3.2 - Minimum low flow prediction equations

| Region | Equation |
|----------------------|--|
| Newfoundland (1-day) | $0.0021 \times \Phi^{-1} \left\{ \frac{(0.1876)^{-1} \text{Ln}[1+0.1876(T^{-1}-0.9581)]}{0.4433} \right\} \times A^{1.1067}$ |
| Newfoundland (7-day) | $0.0027 \times \Phi^{-1} \left\{ \frac{(0.1849)^{-1} \text{Ln}[1+0.1849(T^{-1}-0.9594)]}{0.4451} \right\} \times A^{1.0848}$ |
| Labrador (1-day) | $0.0011 \times \Phi^{-1} \left\{ \frac{(0.2083)^{-1} \text{Ln}[1+0.2083(T^{-1}-0.9696)]}{0.2888} \right\} \times A^{1.1225}$ |
| Labrador (7-day) | $0.0013 \times \Phi^{-1} \left\{ \frac{(0.2189)^{-1} \text{Ln}[1+0.2189(T^{-1}-0.9676)]}{0.2926} \right\} \times A^{1.1075}$ |

Note:

Φ is the cumulative distribution function of the standard normal distribution

A is the area of the watershed

T is the return period

4 ILLUSTRATED EXAMPLE

The following instructions are to show how to use the Newfoundland and Labrador Low Flows Calculation sheet:

The complete sheet which will be seen when opening the calculator as shown below (Figure 4.1). The left section with the tables is where drainage areas are entered and low flow values are received. The text on the right explains how to use the calculation sheet and what the return values mean.

Newfoundland and Labrador Low Flows Estimation Calculator

How the Low Stream Flows Calculation Sheet Works:

Next to the "Drainage Area" box (the yellow colour), enter the drainage area of the point of interest, of river in square kilometres (km²) for which the low flow is wanted. If it is a river on the island of Newfoundland enter "Newfoundland" next to the "Region" box (the orange colour), if the river is in Labrador enter "Labrador" next to the region box (the orange colour). Once the area is entered the table will show the Newfoundland one and seven day low stream flows or the Labrador one and seven day low stream flows for return periods of 2, 10, 20, 50 and 100 years. These values will be given in cubic-metre per second (m³/s).

This Low Flows Calculation sheet is based on a 2012 M. Eng. thesis entitled "Low Flow Frequency Study for Newfoundland and Labrador" written by Shabnam Mostafaei Zadeh.

What it all means:

For each area entered there will be 20 different low flows calculated.

Newfoundland vs Labrador - For the study the Province of Newfoundland and Labrador was split up into two homogenous regions: 1) island of Newfoundland and 2) Labrador. Meaning low stream flow predictions for the island (Newfoundland) are different for those of mainland (Labrador).

One Day vs Seven Day Flow - One Day flow means the minimum low flow for a given day whereas seven day flow means the minimum daily average low flow for a seven day period.

Return Periods - how often a low stream flow occurs. For example a 2 year low flow means the stream will have a flow approximately that low every 2 years. In other words there is a 50% chance of there being a 2 year low flow every year. The higher the return period, the lower chance there will be a flow that low in a given year.

Figure 4.1 – The Complete Estimation Sheet

The location of the river will be entered in the location cell (orange). If low flow is wanted of a stream on the island of Newfoundland enter Newfoundland (see Figure 4.2). If it is in Labrador enter Labrador (see Figure 4.3).

Region Newfoundland

Drainage Area km²

| Return Period (Years) | Labrador | |
|-----------------------|--------------------------------|--------------------------------|
| | 1 Day Flow (m ³ /s) | 7 Day Flow (m ³ /s) |
| 2 | 0.00 | 0.00 |
| 10 | 0.00 | 0.00 |
| 20 | 0.00 | 0.00 |
| 50 | 0.00 | 0.00 |
| 100 | 0.00 | 0.00 |

Figure 4.2 – Newfoundland being entered into the location cell

Region Labrador

Drainage Area km²

| Return Period (Years) | Labrador | |
|-----------------------|--------------------------------|--------------------------------|
| | 1 Day Flow (m ³ /s) | 7 Day Flow (m ³ /s) |
| 2 | 0.00 | 0.00 |
| 10 | 0.00 | 0.00 |
| 20 | 0.00 | 0.00 |
| 50 | 0.00 | 0.00 |
| 100 | 0.00 | 0.00 |

Figure 4.3 - Labrador being entered into the location cell

Once the location is entered, the drainage area of the point of interest will be entered in the Drainage Area cell (yellow). Once the area is entered the low flow values will appear in the table. The drainage area for the Gander River, in Newfoundland, is shown being entered into the calculator in Figure 4.4. The drainage area of the Ugjoktok River, in Labrador, is shown in Figure 4.5 being entered into the calculator.

| | | | | | |
