SITE SPECIFIC WATER QUALITY OBJECTIVE FOR SELENIUM

EXECUTIVE SUMMARY

Selenium is a naturally occurring nutrient that is essential for health of humans and animals; it accumulates in aquatic organism tissue through dietary update. If concentrations are excessive, adverse effects linked to selenium accumulation in aquatic species can occur, particularly in fish and aquatic birds exposed through feeding on aquatic life. This most sensitive effects occur in early life stages through maternal transfer to eggs and include reproductive impairment, offspring abnormalities, and juvenile mortality. Several factors can contribute to increased selenium accumulation in aquatic ecosystems, including natural water chemistry, water stagnation, and the amount and dominant form of additional selenium released in surface waters.

To predict risks of selenium under future development scenarios for the Kami Iron Ore Mine Project, our team investigated both the predicted increases of selenium and the consequences of those increases on health of aquatic life. Lorax Environmental conducted water quality modelling for the Project as part of the Environmental Assessment (EA); they projected selenium concentrations in Dulley Lake slightly above the current federal water quality guidelines for total selenium (1 µg/L). Using this information, a desktop investigation was used to develop site-specific water quality objectives for selenium.

Concentrations in fish tissue provide the most reliable means of evaluating selenium health risks because the variability in effect levels is lower when expressed as a tissue measurement rather as a water concentration. Methods used to assess site-specific water quality objectives for selenium included the analysis of paired selenium concentrations in surface water and fish tissue from another iron mine (Bloom Lake Project) located in Northern Quebec and operated by Champion Iron. Effluent quality from the Bloom Lake Project is broadly similar to projected effluent quality for the Kami Project and serves as a proxy to estimate selenium accumulation potential in Duley Lake fish. Selenium concentrations in fish (white sucker) muscle and egg-ovaries were divided by selenium concentrations in water to calculate regional bioaccumulation factors. Bioaccumulation factors were then multiplied by predicted maximum water quality projections for selenium (1.2 µg/L) at Duley Lake to estimate concentrations in resident fish species for Duley Lake (e.g., Lake Trout). For context, bioaccumulation factors were also multiplied by the generic water quality guideline values of 1 µg/L (CCME 2003), 1.5 µg/L (USEPA 2016), and 2 µg/L (BC ENV 2014). These exposure calculations yielded estimated fish tissue concentrations associated with a low likelihood of adverse effects. Estimated selenium concentrations in fish tissue were then compared to available selenium benchmarks in fish tissue: whole-body (6.7 and 8.5 mg/kg dry weight), muscle (11.5 and 14.3 mg/kg dry weight), and egg-ovaries (14.7 and 20 mg/kg dry weight). These tissue benchmark values are considered protective of fish species from North America and were used to estimate risks associated with selenium exposure.

Our assessment demonstrated that under a scenario of chronic exposure to selenium at federal guideline value of 1 µg/L in surface waters, estimated tissue concentrations are below tissue benchmarks (negligible risk). Under selenium concentrations at or above 2 µg/L (BC ENV 2014), estimated concentrations in fish tissue slightly exceeded these protective tissue benchmark values. Considering this result and acknowledging the screening level of the analysis (i.e., conservative assumptions used in the face of uncertainty), the generic water quality guideline value of 1.5 µg/L from USEPA (2016) was selected as an interim site-specific water quality objective protective against long-term effects of selenium. The 1.5 µg/L value is based on average selenium concentrations in surface waters over a 30-d period, and the recommended frequency of exceedance is once every three years on average.

1.0 INTRODUCTION

This technical memorandum presents the derivation of a proposed site-specific water quality objective (SSWQO) for selenium in support of the Environmental Assessment (EA) for the Kami Iron Ore Mine Project ("Kami Project"), located in Western Labrador. A desktop-based derivation was used as the basis for the SSWQO that builds on regional data collections and provides sufficient conservatism for water management without requiring a supplemental program of site-specific testing. This memorandum summarizes the methods and results of the desktop review, which included a review of recent literature and existing monitoring data for Long Lake (herein referred to as Duley Lake) and an exposure site from the Bloom Lake Project in Northeastern Quebec.

The Site-specific Water Quality Objective (SSWQO) for selenium derived herein applies conservative assumptions in the face of uncertainties; the SSWQO is considered interim given that additional studies could support a higher value. We have not proposed to conduct supplemental investigations at this time because our understanding is that the proposed water management for the Kami Project will satisfy the SSWQO, providing sufficient confidence that no meaningful Project-related effects to ecological resources will occur from selenium exposure.

2.0 BACKGROUND

Site-specific water quality objectives are toxicologically based benchmarks that are protective of aquatic health endpoints and are developed using established science-based procedures for derivation. SSWQOs are customized to the conditions that are applicable to a region or site; they represent substance concentrations that are not predicted to impair ecological health, through either disruption of ecological functions or adversely affecting populations of valued organisms. The SSWQOs have a lower margin of safety relative to generic water quality guidelines (WQG) but retain an appropriate level of conservatism for the evaluation of population-level effects, which would require concentrations to exceed SSWQOs. The customization of SSWQOs to site-specific conditions, including the level of protection afforded to populations and communities, reflects an application of the process of refinement developed by the Canadian Council of Ministers of the Environment (CCME 2007).

Selenium (Se) was identified as a constituent of potential concern (COPC) during the initial phase of the Environmental Assessment through review of the Duley Lake water quality projections provided by Lorax Environmental (Lorax Environmental Services Ltd.). During subsequent conversations with Champion Iron, WSP was requested to submit a proposal for establishing an interim Se SSWQO for Duley Lake, relying primarily on a desktop review approach using monitoring information from a surrogate iron mine in the region (i.e., Bloom Lake Project) operated by Champion Iron in Northern Quebec, with similar effluent composition as the Kami Project. Reliance on regional information was appropriate given that it considers regional factors governing the bioavailability and uptake of Se and provides more information on tissue-based Se exposures relative to the limited baseline information for the receiving environment of Duley Lake. Our analysis also considered the ongoing development of water quality projections for the Kami Project, for which refinements are being made in

parallel to this Se scope of work. This memorandum presents a summary of the methodology (Section 3.0), results (Section 4.0), uncertainties (Section 5.0), discussions (Section 6.0), and conclusions (Section 7.0) for the proposed Se SSWQO.

3.0 METHODS

The scope of work used to derive the Se SSQWO incorporated a review on Se bioaccumulation potential in fish tissue and a literature review of relevant toxicity thresholds. Due to the principal mechanism of action of toxicity for Se in aquatic environments being strong linked to tissue uptake, the literature review considered both aqueous exposures and tissue benchmarks, with the objective being to derive protective concentrations for Se in surface water. General methods included a desktop review of bioaccumulation potential using monitoring information from a surrogate iron mine, Bloom Lake Project, operated by Champion Iron in Northern Quebec approximately 20 Km away from the Kami Project. The Bloom Lake Project exposure site (i.e., Mazaré Lake) was used as a surrogate as there is currently limited baseline Se bioaccumulation information for Duley Lake, and the former has a similar effluent composition as the Kami Project. The scope of work included the following two phases:

- **Phase 1: Desktop review for benchmark development—**This phase reviewed historical environmental monitoring data from Mazaré Lake (e.g., water quality, fish tissue quality, and sediment quality) and review of current baseline conditions at Duley Lake, including resident fish species and fish habitat. In addition, we reviewed published information on Se bioaccumulation and toxicity to freshwater fish (emphasis was given to cold-water fish species) and available chronic guidelines for Se in North America.
- **Phase 2: Development of interim Se SSWQO—**Findings from Phase 1 guided the development of an interim SSWQO. Due to the overall low baseline Se concentrations in surface water and fish tissue from Duley Lake, a literature-based approach, in a format similar to USEPA 2016[1], was used to estimate the risks of Se to the receiving environment. This approach included:
  - Compiling environmental monitoring data from a surrogate iron mine site, Bloom Lake Project, operated by Champion Iron, with similar effluent characteristics as projected for the Kami Project, and similar regional conditions of ecology and several limnological factors.
  - Calculating region-specific bioaccumulation factors (BAFs) based on paired aqueous Se concentrations and tissue concentrations measured in sentinel fish species collected at Bloom Lake Project exposure site (i.e., Mazaré Lake).
  - Applying region-specific BAFs to estimate Se bioaccumulation in fish tissue using chronic water quality guidelines and effluent projections for the different Kami Project phases (operational, closure, and post-closure), including different locations within the receiving environment (i.e., initial dilution zone [IDZ], mid-lake, and lake outflow).
  - Comparing predicted Se concentrations in fish tissue against available tissue benchmarks for selenium to estimate risks and develop an interim SSWQO.
  - Scaling of the protective tissue-based benchmark for Se to an estimated aqueous concentration (interim SSWQO) applicable to Duley Lake.

[1] United States Environmental Protection Agency (USEPA). 2016. Aquatic Life Ambient Water Quality Criterion for Selenium in Freshwater 2016 – Fact Sheet. Available at: https://www.epa.gov/sites/default/files/2016-06/documents/se_2016_fact_sheet_final.pdf

4.0 RESULTS

4.1 Desktop Review

This section describes the key findings of the desktop review of the following:

- Available chronic guideline values for selenium (water, sediment, and tissue) developed by several jurisdictions in North America
- Environmental toxicity modifying factors (ETMFs; biotic and abiotic) influencing Se bioaccumulation and toxicity to fish species
- Available environmental monitoring data (water quality and fish tissue) for Duley Lake and Mazaré Lake
- Documentation of resident fish species, habitat, trophic position, and sensitivity to selenium at Duley Lake
- Water quality projections (model version v2 submitted by Lorax on 05 February 2025) for Duley Lake including the operational, closure, and post-closure phases

4.1.1 Available Chronic Selenium Guidelines in North America

To account for Se bioaccumulation potential in aquatic ecosystems, several generic guidelines have been derived in North America; these guidelines are based on no-effect threshold concentrations for Se in fish tissue (and aquatic bird eggs) as a preferred exposure metric rather than aqueous Se exposure. The reliability of tissue-based benchmarks is greater than aqueous exposure benchmarks given that many site-specific factors can govern the uptake and toxicity of Se. Typically, chronic Se criteria in surface waters consider an average monthly exposure duration, whereas tissue data integrate spatial and temporal aqueous Se exposure over time representing a Se steady-state (i.e., equilibrium) and also reflect the factors like speciation, nutrients, and hydrological factors that influence bioaccumulation and toxicity of Se. The available chronic guideline values for selenium in North America (water, sediment, and tissue) are summarized in Table 1.

Table 1: Chronic Guidelines for Selenium in North America

Environment	Units	CCME/ ECCC	Year	BC ENV	Year	USEPA	Year
Water (Lentic)	µg/L	1	2003	2	2014	1.5[b]	2016
Water (Lotic)	µg/L	1	2003			3.1[b]	2016
Water (Alert Concentration)[a]	µg/L	—	—	1	2014	—	—
Sediment	mg/kg dw	—	—	2	2014	—	—
Biota							
Benthic Invertebrates	mg/kg dw	—	—	4	2014	—	—
Fish							
Eggs/ovaries	mg/kg dw	14.7	2022	11	2014	15.1[c]	2016
Whole Body	mg/kg dw	6.7	2022	4	2014	8.5[c]	2016
Muscle	mg/kg dw	—	—	4	2014	11.3[c]	2016
Bird Eggs	mg/kg dw	11	2022	6	2014	11.2[c]	2024

Notes: CCME= Canadian Council of Ministers of the Environment; ECCC = Environment and Climate Change Canada; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; USEPA = United States Environmental Protection Agency.
µg/L = micrograms per liter; mg/kg dw = milligrams per kilogram of dry weight.
[a)] The Alert Concentration is a concentration below the British Columbia Water Quality Guideline (BC WQG) but above which there may be some risk to some environments and/or species that are particularly sensitive to selenium bioaccumulation. If the alert concentration is exceeded, a series of actions may be triggered to evaluate whether impacts may be occurring and if necessary, mitigate the effects of, selenium.
[b)] Water column criterion is based on a monthly average exposure duration of 30 days.
[c)] Tissue elements are provided as steady-state and indicate instantaneous point measurements that reflect the integrative accumulation of Se in populations over time and space at a given site.

4.1.2 Factors Influencing Selenium Bioaccumulation and Toxicity in Aquatic Systems

Selenium (Se) is an essential micronutrient found in various forms in aquatic ecosystems, including elemental (Se^0), selenide (Se^{2-}), selenate (Se^{6+}), selenite (Se^{4+}), and organic compounds (Chapman et al. 2010). In oxygen-rich waters, Se is typically present in the form of selenate or selenite. Aqueous Se speciation associated with industrial releases varies among sectors; selenite is primarily linked to coal-fired power plants and oil refineries, whereas selenate is associated with metal mining runoff (ECCC and Health Canada 2017). Microorganisms at the base of the aquatic food webs (e.g., microalgae, bacteria, and fungi) incorporate dissolved inorganic Se, and convert it into organic forms that can be transferred to higher trophic levels via diet (Janz et al. 2010).

The degree of trophic magnification of Se is typically greatest at lower trophic levels; additional biomagnification occurs in higher trophic levels but with lower trophic transfer factors (Presser and Luoma 2010). Toxicity to fish is primarily dictated by dietary Se intake and accumulation in tissue (i.e., especially egg-ovaries) relative to aqueous Se exposure (i.e., no direct exposure contact). Due to the maternal transfer of Se to eggs, and associated reproductive effects to offspring, the most vulnerable period for exposure in fish is when they are producing eggs (Lemly 1993; Penglase et al. 2014). Consequently, the toxic effects of chronic exposure to Se are usually associated with early juvenile stages, causing embryotoxicity, teratogenesis, and mortalities (Ohlenhof 2002). Fish sensitivity to dietary Se exposure varies among species and can be affected by factors including feeding behaviour, developmental stage, age, and size (Stewart et al. 2010).

Biotic and abiotic factors are known to affect Se bioaccumulation in aquatic food webs, including:

- **Water chemistry**—The presence of metals, nutrients, and major ions (e.g., mercury, arsenic, sulphate, nitrate and phosphate) can interfere with Se uptake by primary producers (Young et al. 2010). Specifically, due to similar molecular structures shared between sulphate and selenate, a strong competition for ionic uptake by primary producers has been reported in the literature between these two compounds, resulting in reduced Se uptake and biotransformation into organic forms under increased sulphate concentrations (DeForest et al. 2017).
- **Water residence time**—Greater water residence time in lentic and stagnant waters facilitates aqueous Se uptake, accumulation, and biotransformation by microorganisms into organic Se forms. Greater organic Se sedimentation (e.g., organic detritus, sediment, biofilms) is typically reported in lentic systems. Conversely, Se accumulation is reduced in lotic systems (i.e., flowing waters). As an example, Se accumulation in primary producers, especially biofilms, is 10- to 100-fold higher in lentic ecosystems (Stewart et al. 2010; Mendes et al. 2023) relative to lotic ones (Young et al. 2010).
- **Community composition**—Differences in primary producer assemblages (i.e., biofilms and phytoplankton) can affect Se assimilation rates. Biofilms tend to accumulate greater Se concentrations relative to phytoplankton (Graves et al 2021). Significant differences in Se accumulation can also occur within natural biofilm communities depending on biofilm composition and dominant taxa (Markwart et al. 2019).
- **Biological productivity & microbial activity**—Higher primary productivity in mesotrophic and eutrophic ecosystems enhances the incorporation of dissolved inorganic Se by microorganisms and conversion into organic forms (Oldach et al. 2022), leading to increased Se transfer and bioaccumulation to aquatic biota (Orr et al. 2006; Young et al. 2010).

4.1.3 Existing Environmental Monitoring Data

4.1.3.1 Water Quality Data from Bloom and Duley Lakes

Information relative to lake size and depths, and water retention time when available, was assessed to compare both lake systems. Bloom Lake Project exposure site (i.e., Mazaré Lake) is a relatively small and shallow water body (maximum depth of 4.5 m), whereas Duley Lake is a large, deep, and stratified lake system (maximum depth of 20 m) with a water retention time and turnover of approximately one year. Available water quality data from 2019–2023 from Mazaré Lake (station ESU-MAZ-EXP-1) were summarized to provide information on the range of concentrations for Se and its antagonists (e.g., sulphate, arsenic, mercury, and phosphate; Table 1—Attachment 1). These data were subsequently compared to water quality projections for Duley Lake (Section 4.1.3.2) to validate the use of this exposure site as a potential surrogate for the assessment of Se trophic transfer and bioaccumulation in fish tissue.

4.1.3.2 Water Quality Projections for Duley Lake

Water quality projections developed by Lorax Environmental for future Project cases were compared to Duley Lake baseline conditions (Table 1; Attachment 2) assessed in 2023 and 2024 to provide information on the expected level of change in water quality during project phases (i.e., operations, closure, and post-closure). The CORMIX model included monthly water quality projections for total and dissolved metals and major ions for operations, closure, and post-closure (Tables 1-3; Attachment 3). The dataset included projections for the initial effluent dilution zone (IDZ), middle of the lake, and lake outlet (i.e., confluence to Walsh River).

Based on the assessment of water quality data from Mazaré Lake and water quality projections for Duley Lake, the following was observed:

- An overall predicted increase in concentrations of water quality constituents, including Se, during operations relative to baseline conditions
- Similar range of Se concentrations in Duley Lake during operations (0.3–1.2 µg/L) relative to Mazaré Lake (0.05–1.3 µg/L)
- Marginal exceedances of CCME guidelines were predicted for total dissolved Se in surface waters (1 µg/L) exclusively during the Project operational phase in Duley Lake, particularly at the IDZ (maximum Se concentrations of 1.2 µg/L)
- Decreasing trend of Se and its antagonists during closure and post-closure phases
- Lower sulphate (median 9.0 mg/L) and nitrate (median 0.4 mg/L) concentrations in Duley Lake relative to Mazaré Lake (median sulphate of 95 mg/L and nitrate of 5.8 mg/L)
- Comparable arsenic and mercury concentrations during operational phase in Duley Lake relative to Mazaré Lake (median sulphate 95 mg/L and nitrate 5.8 mg/L)
- Comparable circumneutral pH (7.4) for baseline conditions at Duley Lake, Kami Project phases, and average pH at Mazaré Lake (7.4).

4.1.3.2 Occurring Fish Species in Duley Lake

Resident fish species in Duley Lake, their respective trophic position, site fidelity, and available information on sensitivity to Se were summarized (Table 2). Baseline studies conducted in 2012 and 2024 (AMEC 2012; WSP 2024) documented observed fish species in Duley Lake. Fish trophic position was obtained through a desktop review on Fishbase[2]. Baseline studies, along with internal discussions with WSP's senior fish biologist James MacCarthy, helped inform species forage range and site fidelity, assessed qualitatively according to fish movement and potential migration to tributaries.

Species sensitivity to Se was assessed from studies used to derive generic fish tissue benchmarks in North America (USEPA 2016, ECCC 2021) and studies reviewed by DeForest et al. (2012) that focused exclusively on occurring fish species in Canada. When species-specific sensitivity data were not available for occurring taxa, available genus-level sensitivity data were used as a surrogate metric to provide context on the potential level of Se sensitivity.

Table 2: Occurring Fish Species, Trophic Position, Site Fidelity, and Sensitivity to Selenium Identified for Duley Lake

Species	Trophic Position	Se Sensitivity	Site Fidelity
Burbot (*Lota lota*)	TL4	NA	moderate-high
Lake Chub (*Couesius plumbeus*)	TL3	NA	moderate-high
Longnose Dace (*Rhinichthys cataractae*)	TL3	NA	moderate-high
Northern Pike (*Esox lucius*)	TL4	moderate	moderate-high
Atlantic Salmon (*Salmo salar*)	TL4	moderate[a]	moderate-low
Brook trout (*Salvelinus fontinalis*)	TL3	moderate	moderate-low
Lake Trout (*Salvelinus namaycush*)	TL3/TL4[b]	moderate[c]	moderate-high
Lake Whitefish (*Coregonus clupeaformis*)	TL3	NA	moderate-high
Round Whitefish (*Prosopium cylindraceum*)	TL3	NA	moderate-high
Mottled Sculpin (*Cottus bairdi*)	TL3	NA	moderate-high
Slimy Sculpin (*Cottus cognatus*)	TL3	NA	moderate-high
Threespine Stickleback (*Gasterosteus aculeatus*)	TL3	NA	high
White Sucker (Catostomus commersoni)	TL3[d]	moderate[e]	moderate-high
Longnose Sucker (*Catostomus catostomus*)	TL3	moderate[f]	moderate-high
Pearl Dace (*Margariscus nachtriebi*)	TL3	NA	moderate-high

Notes: TL3= trophic position equivalent to tertiary consumers (omnivorous fish); TL4= trophic position equivalent to quaternary consumers (apex predators). NA: information not available
[a)] Classification based on data available for species Brown trout (genus *Salmo*) corresponding to a single study in which an EC06 or NOEC was estimated at 20.8 µg/g dw.
[b)] Juvenile lake trout generally eat plankton, insects, and small invertebrates, whereas adults prefer to eat fish. Some lake trout populations feed on plankton throughout their lives and attain smaller sizes than their piscivorous, or fish-eating, counterparts.
[c)] Classification based on data available for occurring species Brook trout (genus *Salvelinus*) corresponding to a NOEC at 20 µg/g dw.
[d)] Feed on lake bottom on worms, clams, insect larvae, and occasionally fish eggs.
[e)] A single study assessed the sensitivity of Se to white sucker with mean egg Se concentrations of 25.6 µg/g dw, resulting in 12.6% larval deformities in fish exposed to mine effluent. Because no information was available at reference sites, a high degree of uncertainty was associated with this value.
[f)] Classification based on data available for occurring species White Sucker (genus *Catostomus*) corresponding to EC13 at 25.6 µg/g dw.

[2] https://www.fishbase.se/identification/SpeciesList.php?genus/

Species sensitivity to Se was classified as high, moderate, or low as follows:

- **High sensitivity**—10% effective concentration (EC_{10}) or no observed effect concentrations (NOEC) at egg Se concentrations less than 20 µg/g dry weight (i.e., corresponding to the 5th percentile of hazardous concentrations [HC_5] for Se in fish eggs-ovaries; DeForest et al. 2012)
- **Moderate sensitivity**—EC_{10} or NOEC at egg Se concentrations 20 to 30 µg/g dry weight
- **Low sensitivity**—EC_{10} or NOEC at egg Se concentrations greater than 30 µg/g dry weight

4.1.3.3 Selenium Bioaccumulation in Fish Tissue

Selenium concentrations in sentinel fish, specifically in white sucker tissue (i.e., muscle and egg-ovaries) collected at Bloom Lake exposure and reference sites in summer 2020 were compiled (Table 3). Measured concentrations in fish muscle were subsequently used to estimate whole-body Se concentrations using literature-based conversion factors (CFs) for this species. Bioaccumulation information from the Bloom Lake exposure site, specifically aqueous Se exposures, measured Se in specific tissues (i.e., muscle, egg-ovaries), and estimated whole body Se concentrations, were subsequently used to calculate bioaccumulation factors (BAF) (Table 3). BAFs were calculated as the ratio of Se tissue concentrations and aqueous Se concentrations:

BAF= Se concentration in fish tissue / Total aqueous Se concentration

To characterize baseline Se concentrations in sentinel fish from Duley Lake (i.e., Lake trout), muscle Se data were used to estimate Se concentration in fish egg ovaries and whole-body fish; this conversion was conducted by applying CFs available for other salmonid species (Table 4). Results indicated similar Se concentrations in fish muscle between the two lake systems, despite the higher aqueous Se at the former (median 1.6 µg/L) relative to the latter (<0.04 µg/L). This outcome suggests that under low-level aqueous Se exposure range (0.04–2.8 µg/L) Se bioaccumulation pattern in fish tissue does not follow a linear trend, as previously reported in the literature (Graves et al. 2021).

Table 3: Selenium Concentrations in Sentinel Fish Tissue for Bloom Lake Project

Fish Species	Lake	Muscle (µg/g dw)	BAF (L/Kg)	Whole-body (µg/g dw)[1]	BAF (L/Kg)	Egg-ovaries (µg/g dw)[2]	BAF (L/Kg)
White sucker (*Catostomus commersonii*)	Lake Mazaré (Exposure)	4.3	7,277	3.21	5,431	6.10	10,323

Notes: µg/g dw = micrograms per gram of dry weight.
Lake trout was sampled on 16 August 2024 and 26 August 2024.
[a)] Conversion factor (CF) used for muscle/whole body calculation of 1.27 (USEPA 2016)
[b)] CF used for Se muscle-egg/ovaries calculations of 1.17, representing the geometric mean of available CFs for the genus *Salvelinus* (*Salvelinus malma* of 1.26 and *Salvelinus fontinalis* of 1.09; USEPA 2016).

4.2 Phase 2: Development of Interim Se SSWQO

In the absence of information on Se concentrations in fish tissue during the Project operational phase, available monitoring data from Mazaré Lake were used to estimate Se bioaccumulation potential in fish tissue from Duley Lake, based on the following assumptions:

- Similar effluent characteristics with a comparable range of Se concentrations to the Project operational phase
- Comparable predominant Se speciation (i.e., selenate) in both Duley Lake and Mazaré Lake
- Proportionally increasing levels of Se antagonists during the Project operational phase (i.e., concentrations of all toxicity modifying factors assumed to increase in direct proportion to Se exposure)

The derivation of Se SSWQO for Duley Lake included five steps:

- Development of a conceptual site model for Se bioaccumulation in a lentic system (Figure 1)
- Review of effects thresholds for Se in resident fish species or surrogate candidates (i.e., same genus) to customize North American tissue benchmarks (Section 4.1.1) to local biological conditions:
  - **Egg-ovaries**—20 µg/g dry weight, representing the HC_5 for occurring fish species in Canada (DeForest et al. 2012), corresponding to the EC10 value for Brook Trout (same genus [*Salvelinus*] as the Duley Lake sentinel fish [Lake Trout]). This no-effect threshold is considered protective of other occurring salmonid genera (i.e., EC10 for *Salmo* at 25.3 µg/g dry weight) and predator species Northern Pike (EC10 at 20.4 µg/g dry weight; ECCC 2021).
  - **Muscle**—14.3 µg/g dry weight, corresponding to the genus mean chronic value (GMCV) for the most Se sensitive salmonid genus *Oncorhynchus* (USEPA 2016); considered protective of occurring salmonid genus *Salmo* in Duley Lake (GMCV at 18.5 µg/g dry weight).
  - **Whole-body**—8.5 µg/g dry weight representing USEPA whole-body criterion (2016) and the EC10 for predator species Northern Pike (8.54 µg/g dry weight; ECCC 2021); the lowest value for occurring species/genus with available data (Table 3).
- Comparison of region-specific BAFs (i.e., derived for Mazaré Lake) to empirically-derived BAFs for lentic and lotic freshwater ecosystems in North America (DeForest et al. 2007).
- Generic chronic water quality guideline values for Se in North America were used in conjunction to by the region-specific BAFs to estimate Se concentrations in whole-body fish, muscle, and egg ovaries.
- Comparison of estimated Se concentrations in fish tissue (whole-body, muscle, and egg-ovaries) to no adverse effects thresholds for Se in fish tissue (i.e., generic tissue benchmarks and selected tissue benchmarks customized for site) to estimate potential risks at Duley Lake.

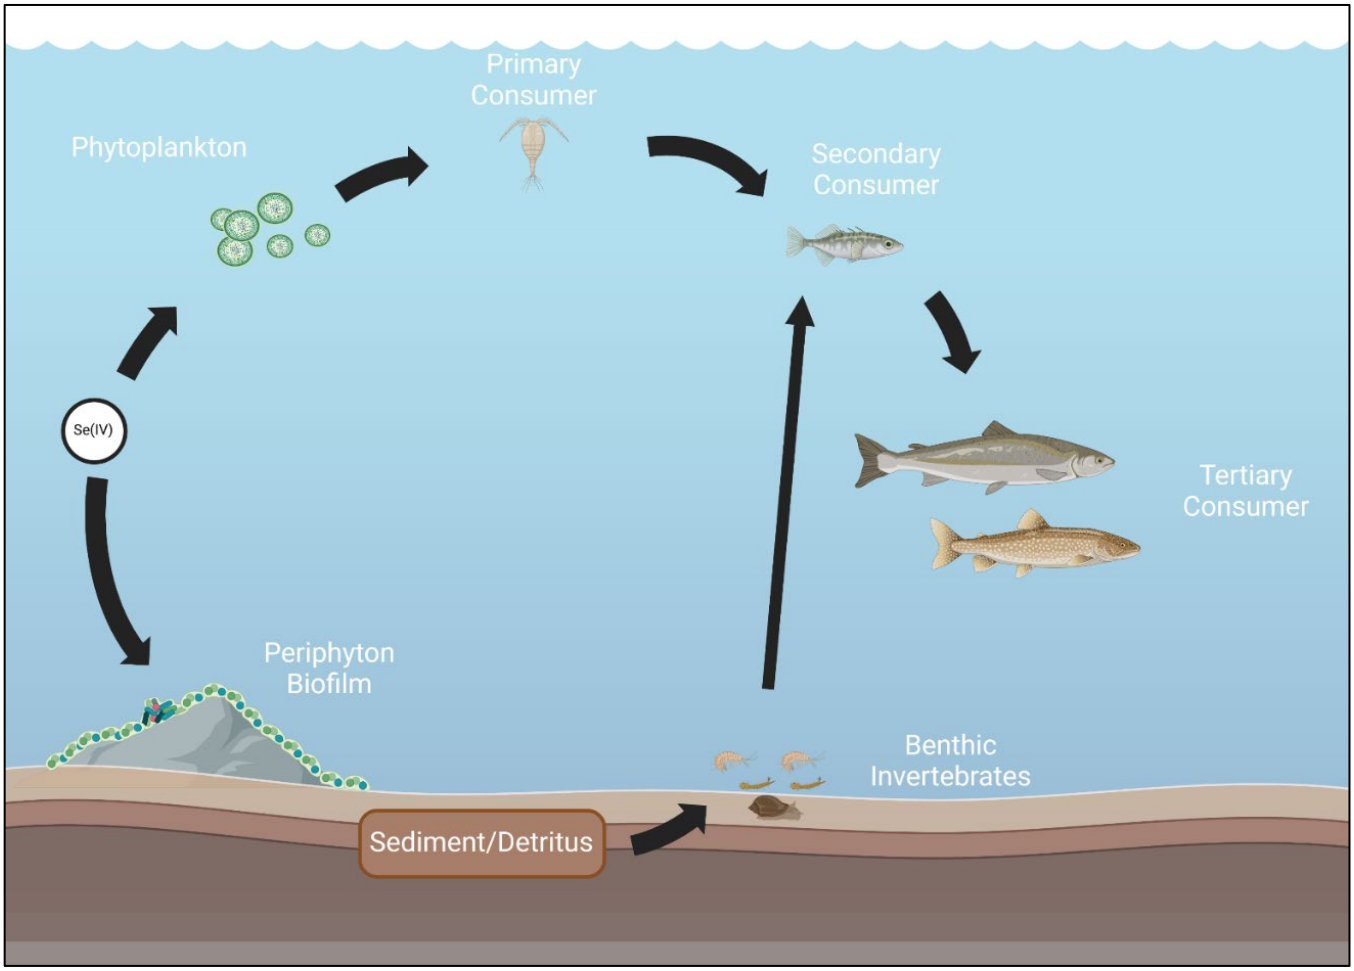

Figure 1: Conceptual site model for Se bioaccumulation in a boreal lake system. Adapted from Graves et al. (2021)

Created in https://BioRender.com

The integration of these five derivation steps yielded the following results:

- Derived region-specific BAFs were within the empirical range for lentic and lotic ecosystems documented in the literature (approximately 3-fold above the geometric mean of empirical BAFs; Table 5). Typically, BAFs from lotic ecosystems are 3-5-fold lower than lentic ones (USEPA 2016). The fact that regional BAFs are above the geometric mean of empirical values is somewhat expected for a lake environment.
- Use of the generic chronic Canadian guideline value of 1 µg/L, in conjunction with the region-specific BAF equation, yielded estimated Se tissue concentrations below the generic tissue benchmarks (Table 6).
- Use of the generic chronic USEPA guideline value of 1.5 µg/L for lentic ecosystems, in conjunction with the region-specific BAF equation, yielded Se tissue concentrations below the customized tissue benchmarks for the site (Table 6).

- Use of the generic chronic BC guideline value of 2.0 µg/L, in conjunction with the region-specific BAF equation, yielded Se tissue concentrations slightly above generic tissue benchmarks and customized whole-body tissue benchmark (Table 6).
- BAFs generated from non-gravid white sucker and applied to all three generic chronic water quality guideline values (CCME, USEPA, and BC MOE) resulted in Se concentrations in egg-ovaries below the HC_5 of 20 µg/g dry weight (Table 6). This tissue benchmark was considered appropriate for protection of resident fish species at Duley Lake, particularly of sensitive salmonids.

Table 5: Comparison Between Empirically Derived and Site-Specific Se Bioaccumulation Factors (BAFs)

BAFs (L/Kg)	Minimum	Geomean	Maximum
Empirical[a]	7	1,531	52,000
Region-Specific BAFs- whole body	4,293	4,868	5,935
Region-Specific BAFs- muscle	5,753	6,524	7,953
Site Specific BAFs- Egg-ovaries	7,446	9,248	10,323

Notes: a) Comprises data for invertebrates and whole-body fish in lentic and lotic ecosystems

Table 6: Comparison of estimated Se tissue concentrations (using region-specific BAFs and chronic Se water quality guidelines) to tissue effect benchmarks for Se

Se Tissue Effect Benchmarks from Literature (µg/g dry weight)		CCME Aqueous WQG (1.0 µg/L)		USEPA Aqueous WQG (1.5 µg/L)		BC MOE Aqueous WQG (2.0 µg/L)	
		Region-specific BAFs (L/Kg)	Estimated Tissue Se (µg/g dry weight)	Region-specific BAFs (L/Kg)	Estimated Tissue Se (µg/g dry weight)	Region-specific BAFs (L/Kg)	Estimated Tissue Se (µg/g dry weight)
Whole-body	6.7[b] / 8.5[c]	4,869	4.9	4,869	<u>7.3</u>	4,869	**<u>9.7</u>**
Muscle	11.5[c] / 14.3[d]	6,524	6.5	6,524	9.8	6,524	<u>13.0</u>
Egg-ovaries[a]	14.7[b] / 20[e]	9,248	9.2	9,248	13.9	9,248	<u>18.5</u>

Notes: <u>Underlined</u> values indicate concentrations above generic tissue benchmarks (whole-body, muscle and egg-ovaries), whereas values in **bold** represent exceedances of tissue benchmarks for Duley Lake.
a) BAF value calculated from non-gravid fish (White Sucker)
b) Canadian tissue benchmark (ECCC 2021)
c) USEPA tissue benchmark (USEPA 2016)
d) GMCV for most sensitive salmonid genus (USEPA 2016)
e) HC_5 derived for occurring fish species in Canada (DeForest et. al. 2012)

Because ovaries are the target organ for Se toxicity causing known adverse effects to fish offspring, these three North American jurisdictions support the preferential use of the egg-ovary analysis (i.e., from gravid fish) relative to other exposure metrics (i.e., egg-ovary > muscle> whole body > aqueous). The use of region specific BAFs in conjunction with all three generic WQ guidelines for Se yield estimated values below the HC_5 of 20 µg/g d.w. for the preferred exposure media (egg-ovaries).

5.0 UNCERTAINTIES

Residual uncertainties associated with the approach adopted to derive interim SSWQOs for Se were categorized based on the magnitude of uncertainty:

- **High—**The largest uncertainties relate to the need to extrapolate information from other studies or locations to the Project Site at Duley Lake. This uncertainty was addressed through use of conservative assumptions regarding the applicability of those results to the Project.
  - Local species sensitivity—The sensitivity of local fish species was unknown for most Duley Lake species; Although the two most sensitive species in the SSD developed by ECCC (2022), specifically Bluegill (*Lepomis macrochirus*) and White Sturgeon (*Acipenser transmontanus*), are not present in Duley Lake, there are representatives of other species that are moderately sensitive to Se. For example, the resident trout species of Brook Trout (*Salvelinus fontinalis*) and Lake Trout (*Salvelinus namaycush*) are reasonable matches to the multiple trout species for which Se toxicity data are available. Furthermore, resident freshwater whitefish of the subfamily Coregoninae (e.g., Lake Whitefish *Coregonus clupeaformis*, Round Whitefish *Prosopium cylindraceum*) and subfamily Salmoninae (e.g., Atlantic Salmon *Salmo salar*) are also salmonids. It is therefore assumed that the sensitivity of Duley Lake fish requires the same broad level of protection as the species used in the development of generic Se guidelines.
  - Interspecies extrapolation in bioaccumulation potential—Interspecific differences may exist between the surrogate White Sucker (Mazaré Lake) and Lake Trout (Duley Lake). Specifically, the potential differences between the trophic position of these two species (i.e., TL3 for White Sucker and TL3–TL4 Lake trout depending on site) could affect comparability BAFs. Fortunately, because trophic transfer factors for Se tend to be small at TL3 and TL4, the magnitude of the differences based on species biology would not be large.
  - Non-linearity of Se bioaccumulation—Because Se can bioaccumulate in a concentration-dependent manner (Graves et al. 2021) there is uncertainty when extrapolating bioaccumulation information over space (i.e., across lakes with different base concentrations of Se), or where changes in Se occur over time within a single lake. Fortunately, given the similar range of Se concentrations in Duley Lake during operations (0.3–1.2 µg/L) relative to Mazaré Lake (0.05–1.3 µg/L), this uncertainty is controlled.
- **Moderate**—Additional uncertainties relate to the specific parameters and measurements used to estimate site-specific bioaccumulation potential:
  - Model predictions for water quality—Modelling of selenium included data for total selenium with assumed predominant selenate species. Selenate is the least bioavailable form for Se uptake subsequent trophic transfer along food webs. Information on the proportion of selenite, and organic selenium species in Duley Lake is relevant to reduce uncertainties around Se bioaccumulation potential.
  - Representativeness of white sucker tissues—Selenium concentrations in egg-ovaries of non-gravid white sucker were used to generate site-specific BAFs for egg-ovaries. Concentrations may be higher or lower in ripe versus non ripe fish ovaries but results depend on species (USEPA 2016, Detering et al. 2025). Despite species-specific differences in Se bioaccumulation in fish egg-ovaries, recent investigations indicated a general inverse relationship in Se concentrations as a function of egg-ovary developmental status (Brix et al. 2025). For salmonid species, such as Rainbow Trout, Brook Trout, and Westslope

Cutthroat Trout, significantly higher Se concentrations in unripe ovaries relative to ripe ones have been reported in the literature (Detering et al. 2025). This outcome suggests that regional BAFs (i.e., calculated based on unripe data) are overestimates of Se exposure in egg-ovaries for the local fish species at the top of the food chain in Duley Lake (e.g., Lake Trout, Atlantic Salmon). However, given the desired level of conservatism for a screening-level assessment, no adjustment was made to the BAFs calculated using unripe ovaries.

- Influence of chemical modifying factors—Differences in overall lake water quality characteristics, including differences between the surrogate exposure site in Bloom Lake and Duley Lake with respect to potential antagonists for selenium uptake, represented a source of uncertainty for calculated BAFs. Fortunately, the differences observed for these parameters between regional lakes were not sufficiently large to substantially influence bioaccumulation. Furthermore, comparison between the range of empirical Se BAFs (DeForest et al. 2007) and site-specific BAFs, indicates that regional conditions reflect typical lentic systems with moderate level of bioaccumulation (i.e., that do not include extremes for Se bioaccumulation, such as stagnant lentic environments that maximize Se bioaccumulation).

Overall, based on the available evidence, the Duley Lake exposure scenarios are likely to be reasonably well described by the bioaccumulation conditions and species sensitivities reflected in the generic water quality guideline derivations in North America. Extreme conditions, such as stagnant wetland conditions with high residence times that biogeochemically favour reduction of Se (Graves et al. 2021), are not applicable to this Site. Our derivation has maintained conservatism with respect to species sensitivity, bioaccumulation potential, and influence of modifying factors; no additional margins of safety are required for this SSWQO derivation.

6.0 DISCUSSION

Selenium concentrations in fish tissue (whole-body, muscle, and egg-ovaries) estimated using Canadian chronic surface water guideline value for total dissolved Se (1 µg/L), in combination with site-specific BAFs from tertiary consumer fish species, yielded values below generic tissue benchmarks for Se in North America. This outcome suggests this generic water quality criterion is likely over-conservative for the protection of aquatic life in the receiving environment of Duley Lake. The use of regional bioaccumulation data and tissue residue effects data provides an improvement in the scientific understanding of risks to aquatic life relative to use of a generic water *quality* criterion.

Based on the analysis of uncertainties and results from estimated Se fish tissue concentrations using region-specific BAFs, the chronic guideline value (SSWQO) of 1.5 µg/L is supported; this value is equivalent to the total dissolved Se guideline for lentic ecosystems specified by USEPA (2016); the SSWQO provides an adequate level of protection for occurring fish species in Duley Lake. This value is based on monthly average exposure for total dissolved Se for a duration of 30 days. It is recommended that the frequency of exceedances of 1.5 µg/L dissolved Se should not occur more than once in three years on average (USEPA 2016). Because the SSWQO was derived based on a robust empirical dataset from multiple lentic ecosystems in North America, it is considered protective of fish species from different trophic levels. Furthermore, the generic chronic Se guideline value of 1.5 µg/L is higher than current maximum water quality projections for total dissolved Se in Duley Lake (1.2 µg/L).

Minor changes to the selenium bioaccumulation potential in Duley Lake may occur over time as a function of future biogeochemical changes, including water quality factors that influence Se uptake. However, given the modest total selenium concentrations predicted for all Project phases, and the lack of likelihood for qualitative changes in receiving conditions (i.e., substantially higher biological activity, higher proportion of selenite, or predominance of reduced aqueous Se species and organo-Se forms), the SSWQO will remain protective under these modified conditions.

7.0 CONCLUSIONS

The proposed interim Se SSWQO for Duley Lake of 1.5 µg/L is protective against long-term effects to aquatic life under site-specific conditions predicted for all phases of the Kami Project. The proposed SSWQO represents a monthly dissolved Se average in surface waters and is based on the Se bioaccumulation potential derived from the surrogate iron mine exposure site (Mazaré Lake) and associated analysis of residual uncertainties. As per the Metal and Diamond Mine Effluent Regulations guidance document (MDMER 2018), the periodic monitoring of Se in sentinel fish tissue during operations (i.e., every three years), will help inform if changes to this interim value are required.

Additional site-specific information gathered during operations, such as aqueous Se speciation to confirm dominant Se species and concentrations of organic forms, as well as Se concentrations in invertebrate tissue (i.e., to determine dietary Se exposure and minimize the lethal sampling of sentinel fish; Palace et al. 2025) is recommended to confirm the appropriateness of the proposed generic chronic guideline value of 1.5 µg/L.

PROPOSED SITE-SPECIFIC WATER QUALITY OBJECTIVE FOR COBALT IN SUPPORT OF ENVIRONMENTAL IMPACT STATEMENT FOR KAMI MINE COMPLEX

EXECUTIVE SUMMARY

This technical memorandum presents the proposed chronic site-specific water quality objective (SSWQO) for total cobalt in support of the Environmental Impact Statement (EIS) for the Kami Iron Ore Mine Project ("Kami Project"), located in Western Labrador. Cobalt is a naturally occurring element and an essential micronutrient required for health of aquatic life. Although the toxic mode of action of cobalt is not fully understood, at high concentrations it can affect enzymes and influence respiration and metabolism. The most sensitive effects are typically observed from direct contact of invertebrates with bioavailable dissolved forms of cobalt.

A desktop-based derivation was used as the basis for the SSWQO that provides sufficient conservatism for water management without requiring a program of site-specific toxicity or biological testing. This memorandum summarizes the methods and results of the desktop review, which included a review of recent literature and water quality projections for Long Lake (herein referred to as Duley Lake) and Pike Lake.

To predict risks of cobalt under future development scenarios for the Kami Iron Ore Mine Project, our team investigated both the predicted increases of total cobalt and the consequences of those increases on health of aquatic life. Lorax Environmental conducted water quality modelling for the Project as part of the Environmental Assessment (EA); they projected total concentrations in Duley Lake slightly above the current federal water quality guidelines for total cobalt (1 µg/L for a hardness of 100 mg/L; 0.83 µg/L for maximum predicted hardness at the edge of the mixing zone in Duley Lake under discharge condition).

The method used to derive an SSWQO followed the federal guidance for development of site-specific objectives. It considered the factors known to influence the toxicity of cobalt in freshwater (e.g., water hardness) and applied curve fitting to reliable and site relevant aquatic toxicity data. The model fit used toxicity data standardized to common water hardness, using a species sensitivity distribution. Our approach assumes that total predicted cobalt comprises mainly dissolved forms of cobalt, a conservative assumption used for screening evaluation.

Using the above approach, the long-term hardness-dependent cobalt SSWQO equation is:

$$SSWQO\ (\mu g/L) = e^{\{0.414[\ln(hardness)]-\ 0.57417\}}$$

This formula yielded site-specific values for total cobalt that ranged between 2.7 and 3.2 µg/L for the affected water bodies (Duley Lake and Pike Lake). Predicted concentrations of cobalt at both lakes remained consistently below this range, therefore the conservatively-derived long-term hardness-dependent cobalt SSWQO equation appears to be suitable for the Kami Iron Ore Mine Project.

1. INTRODUCTION

SSWQOs are toxicologically-based benchmarks that are protective of aquatic health endpoints, and are developed using established science-based procedures for derivation. SSWQOs are customized to the conditions that are applicable to a region or site; they represent substance concentrations that are not predicted to impair ecological health, either through disruption of ecological functions or adverse impacts to populations of valued organisms. The SSWQOs have a lower margin of safety relative to generic water quality guidelines (WQG) but retain an appropriate level of conservatism for the evaluation of population-level effects, which would require concentrations to exceed SSWQOs. The customization of SSWQOs to site-specific conditions, including the level of protection afforded to populations and communities, reflects an application of the process of refinement developed by the Canadian Council of Ministers of the Environment (CCME 2007).

Cobalt was identified as a constituent of potential concern (COPC) during the initial phase of the Environmental Assessment through review of the Duley Lake water quality projections provided by Lorax (Lorax Environmental Services Ltd.). Cobalt concentrations were screened relative to generic ambient water quality guidelines, and during subsequent conversations with Champion Iron, WSP was requested to establish an interim chronic cobalt SSWQO for Duley Lake. Pike Lake (located approximately 5 kilometers away) was also included in this derivation as cobalt concentrations may be above generic guidelines during the post-closure phase of the mine.

This memo presents a summary of the methodology (Section 2), results (Section 3), and conclusions (Section 4) for the proposed chronic total cobalt SSWQO. Detailed methodology and results are presented in Attachment 1.

2. METHODOLOGY

Chronic toxicity data were compiled, evaluated, and used to derive a literature-based SSWQO for total cobalt. Detailed methodology and results are presented in Attachment 1 and included:

1) Consideration of exposure and toxicity modifying factors (ETMFs; Attachment 1, Section 1-2)—hardness is considered by Environment and Climate Change Canada (ECCC) to be the most influential ETMF for cobalt toxicity (ECCC 2017). Hardness was therefore incorporated into the SSWQO derivation.

2) Consideration of existing chronic guidelines (Attachment 1, Section 1-3)— A review of applicable provincial (British Columbia [BC]) or federal (CCME, ECCC, United States Environmental Protection Agency [US EPA]) long-term/chronic freshwater guidelines was undertaken to evaluate existing chronic guidelines for cobalt and the basis for their derivation.

3) Compilation and screening of site-relevant chronic toxicity data (Attachment 1, Section 1-4.1)—compilation and screening of chronic toxicity data for inclusion in the SSWQO dataset was performed per CCME (2007) protocol as follows:

- Data were included for site-relevant species, including surrogate species for those known or suspected to be present in the region. Data were excluded for tropical and saltwater species because they are not ecologically relevant for the site. Other species were included as potential representatives for site-resident species, even if not documented in local monitoring data.
- Minimum dataset requirements for a preferred (Type A per CCME protocol) derivation were met for both number and type of receptors; the cobalt dataset included at least three fish species (including a sensitive salmonid species), six aquatic or semi-aquatic invertebrates (including a planktonic crustacean), and four freshwater vascular plant or freshwater algal species.
- Biological endpoints were selected for growth, reproduction, mortality, and development. Non-traditional endpoints (molecular markers, behaviour, swimming speed) were excluded per established guidance for ecological risk assessment (ECCC 2022).
- Studies were excluded if they were conducted under field conditions of contaminant mixtures (multiple stressors present), did not meet data quality requirements per CCME (2007) study ranking, or evaluated synergistic, antagonistic, or compensatory responses of organisms.
    - Preferred statistical test endpoints per CCME (2007) hierarchy were selected where available[1].
    - Where multiple effect concentrations were available for a single species and related endpoint type, data were combined per CCME (2007) protocol and following guidance from Chapman (2015) using geometric means to calculate a species mean chronic value (SMCV).

4) Derivation of a Type A species sensitivity distribution (SSD) per CCME (2007) procedures (Attachment 1, Section 1-4.2):

- Type A species SSDs were generated in accordance with CCME (2007) protocols to derive a hazard concentration at the 5th percentile (HC_5)[2].
- The BC ENV SSDtools package (Thorley and Schwarz 2018) in R (version 4.2.1; R Core Team 2022) was used to develop the curve fits and numerical endpoint calculations from SSDs.

5) Deriving a hardness-dependent chronic SSWQO per CCME (2007) procedures (Attachment 1, Section 1-5):

- The HC_5 was retained and a hardness-dependent crhonic SSWQO equation was derived for the Kami Iron Ore Mine complex, and the CCME (2007) protection clause[3] was evaluated.

[1] Preferred endpoints in order of most to least preferred per CCME (2007) protocol was as follows: EC_x/IC_x > EC_{10}/IC_{10} > EC_{11-25}/IC_{11-25} > MATC > NOEC > LOEC > EC_{26-40}/IC_{26-40} > nonlethal EC_{50}/IC_{50}. EC_X = effective concentration causing X% reduction in sublethal endpoint with binomial outcomes for individual organisms, such as survival or normal development; IC_X = the concentration that results in a magnitude of effect of X% over a specified period of time; MATC = maximum acceptable toxicant concentration (calculated as the geometric mean of the no observed effect concentration and lowest observed effect concentration; NOEC = no observed effect concentration; LOEC = lowest observed effect concentration.

[2] HC_5 is the hazardous concentration to 5% of the tested species, or the concentration that protects 95% of the tested species.

[3] As discussed in CCME (2007), the protection clause can be invoked if: 1) the derived HC_5 does provide adequate protection of individual species of special concern; or 2) acceptable lethal effects endpoint (i.e., LC_X, where x ≥15%) for any species is lower than the proposed guideline. If either one of these occurs, then the lowest applicable endpoint concentration is applied as the guideline value even if below the HC_5.

3. RESULTS

Results of the data compilation and SSWQO derivation are detailed in Attachment 1. This section provides a high-level overview of key findings.

3.1. Data Compilation

ECCC (2017) compiled, reviewed, and ranked chronic toxicity data for cobalt to generate an SSD that was adjusted for hardness. This dataset was used as the starting point for this compilation and was supplemented by a review of previous northern mining projects and a literature search using the US EPA ECOTOX Knowledgebase (US EPA 2020) and Google Scholar.

The minimum dataset requirements were satisfied for the derivation of an SSD-based (i.e., Type A) SSWQO for freshwater environments as defined by CCME (2007). Chronic toxicity data for the cobalt dataset were retained for 13 species: three fish species (including a sensitive salmonid species), six aquatic or semi-aquatic invertebrates (including a planktonic crustacean), and four freshwater vascular plant or freshwater algal species.

Based on results from the combined datasets, the duckweed *Lemna minor* is the most sensitive organism to cobalt (7-day EC_{10} = 6.3 µg/L hardness normalized). Overall, algae is most sensitive receptor group, followed by invertebrates, and then fish.

3.2. Proposed Interim SSWQO

The SMCVs for cobalt in Attachment 1 (Table 1-2) were used to develop the SSD. The resulting hardness-normalized HC_5 value for cobalt for the compiled chronic toxicity dataset is 3.79 µg/L.

This hardness-normalized HC_5 value was used to derive the long-term cobalt SSWQO equation, based on the procedure used in ECCC (2017). Because water hardness decreases cobalt toxicity to freshwater aquatic organisms (ECCC 2017), the proposed interim SSWQO is expressed as a hardness-dependent equation. The SSWQO equation is based on the toxicity hardness-relationship (i.e., the slope 0.414 derived by ECCC [2017]) and the HC_5 value of 3.79 µg/L (normalized at 100 mg/L as $CaCO_3$ hardness; derived in the SSD Section 1-5.2). The hardness-dependent SSWQO equation is derived as:

$$SSWQO\ (\mu g/L) = e^{\{0.414[\ln(hardness)]+\ y-intercept\}}$$

The y-intercept was calculated as follows (ECCC 2017):

$$y\ intercept\ = \ln(HC_5) - (hardness\ slope \times \ln(hardness))$$

$$y\ intercept\ = \ln(3.79) - [0.414 \times \ln(100)]$$

$$y\ intercept\ = -0.57417$$

where HC_5 is calculated from the SSD (3.79 µg/L), slope is calculated in the hardness adjustment (0.414), ln is the natural logarithm function, and hardness is measured in $CaCO_3$ equivalents (100 mg/L).

Using the calculations outlined above, the long-term hardness-dependent cobalt SSWQO equation is:

$$SSWQO\ (\mu g/L) = e^{\{0.414[\ln(hardness)]-\ 0.57417\}}$$

As stated in ECCC (2017) this long-term SSWQO was calculated over a hardness range of 52 to 396 mg/L as $CaCO_3$, which corresponds to the hardness range over which the pooled slope value of 0.414 was used by ECCC (2017). The above equation and predicted hardness conditions were then used to generate SSWQO values for low flow (25th percentile annual precipitation [P25]), high flow (75th percentile annual precipitation [P75]), and average flow (mean annual precipitation [MAP]) projections[4] during construction, operations, closure, and post-closure at the Kami Iron Ore Mine Complex (Lorax Environmental 2025) for both Duley and Pike Lake. Hardness ranged from 45 to 65 mg/L as $CaCO_3$, which overlaps the lower bound for which ECCC derived the pooled slope value of 0.414. Given that the maximum difference was marginal (14%), the ECCC (2017) equation was retained as reliable, and used to derive SSWQO values for the three flow scenarios (P25, MAP, P75) and the four project phases (construction, operations, closure, and post-closure).

The hardness-dependent SSWQOs for evaluated project cases were similar, ranging from 2.7 to 3.2 µg/L, whereas maximum predicted total cobalt concentrations were ≤2.34 µg/L across all modelled precipitation years and project phases for both lakes. The protection clause in CCME (2007)[5] was evaluated and was not triggered.

As a check on the protectiveness of the derived SSWQO, recent SSD derivations by other authors were reviewed. In comparison to older guideline derivations (discussed further in Attachment 1, Section 1-3), Stubblefield et al. (2020) recently derived chronic guidelines using either the European-based SSD approach (EC_{10} preferred endpoint) or the US EPA-style final chronic SSD value (FCV; EC_{20} preferred endpoint) and calculated HC_5 values of 1.8 µg/L and 7.1 µg/L, respectively. These benchmarks were not normalized to water hardness and reflect minor data processing differences that are jurisdiction-specific, but they reflect derivations broadly compatible with ECCC (2007) methods. The observation that our SSWQO falls within the Stubblefield et al. (2020) range of calculated HC_5 values strengthens confidence in our derivation.

Given that recent literature points to hardness being an important ETMF, our derivation marks an improvement in the customization of the cobalt SSWQO to site-relevant conditions. Our hardness-normalized HC_5 of 3.79 µg/L (using a blend of EC_{10} and EC_{20} values, depending on statistical significance) and the long-term hardness-dependent cobalt SSWQO equation are considered protective of aquatic life in the receiving environment.

4. CONCLUSION

The proposed long-term hardness-dependent SSWQO equation for total cobalt using the Type A SSD derived HC_5 of 3.79 µg/L is protective against long-term effects to aquatic life under site-specific conditions in the receiving environment. The SSWQO dataset is adequately robust (13 species from three aquatic receptor groups). Additional site-specific toxicological testing could be undertaken to expand the dataset used in this derivation, but is not currently required given the adequate coverage of sensitive indicator organisms. Should water quality predictions change, or uncertainty develop around the ability to meet the interim SSWQO, detailed site-specific benchmarks could be developed to manage cobalt in the receiving environment. Such refinements could evaluate the modifying factors at the edge of the mixing zone and confirm bioavailability and toxicity through site-specific toxicity testing.

[4] Calcium and magnesium projections were provided by Lorax (Kami_v19_All_Model_Data_Output_V2.xlsx) on 7 March 2025. These values were used to calculate projected hardness as (Ca × 2.497) + (Mg × 4.118).

[5] The protection clause evaluates whether the species at the extreme lower tail of the SSD require additional protection due to their importance as a sentinel species of higher ecological importance or status as a federally listed Species at Risk.

ATTACHMENT 1

Supplementary Information for Proposed Benchmark Derivation

1-1 CHEMICAL FORM AND BIOAVILABILITY

Cobalt is essential in trace amounts and can exist in six oxidation states; however, the most common states in the aquatic environment are trivalent cobalt (Co^{3+}) and divalent cobalt (Co^{2+}), which form numerous organic and inorganic salts. Like most metals, the solubility of cobalt is highly dependent on its form. Whereas cobaltous carbonate is highly insoluble in water, several salts, such as cobalt chloride ($CoCl_2$), are highly soluble. The soluble salts of cobalt are commonly used in laboratory toxicity tests, which yields conservative estimates of toxicity potential for estimating potential responses under natural (field) conditions.

1-2 EXPOSURE AND TOXICITY MODIFYING FACTORS ($ETMF_S$)

Hardness is considered the most influential environmental and toxicity modifying factor (ETMF) for cobalt toxicity (Environment and Climate Change Canada [ECCC] 2017), with higher toxicity generally observed at lower hardness (Diamond et al. 1992; Borgmann et al. 2005; Parametrix 2010a,b,c). ECCC (2017) concluded that there were sufficient data to evaluate hardness dependence for two species (crustacean *Ceriodaphnia dubia* and fathead minnow *Pimephales promelas*; Parametrix 2010b,c), as a systematic decrease in toxicity with increased hardness was observed for these species. ECCC (2017) noted that pH may also influence cobalt toxicity, but its effect on sensitivity is limited and experimental results were contradictory (Parametrix 2010b,c; Nautilus 2009). Among pH, dissolved organic carbon (DOC), and hardness, the latter is the most important ETMF and accounts for approximately 85% of the variability in observed responses in *C. dubia* and *P. promelas* (Parametrix 2010b,c).

1-3 EXISTING GUIDELINES

A review of applicable provincial (British Columbia Ministry of Environment and Parks [BC ENV]) or federal (ECCC, Canadian Council of Ministers of the Environment [CCME], and United States Environmental Protection Agency [US EPA]) long-term/chronic freshwater guidelines was undertaken to assess the status of generic chronic guidelines for cobalt (Table 1-1).

Table 1-1: Overview of Generic Long-Term (Chronic) Water Quality Guidelines for Cobalt

Exposure Type	Guideline Agency	Guideline Value (µg/L)	Description of Guideline
Chronic	ECCC (2017) FEQG	0.83[a, b]	■ SSD-based guideline with normalization to hardness ■ EC_{10} preferred endpoint ■ Many EC_{10} values fall below the NOEC
	EU HC_5 method (Stubblefield et al. 2020)	1.8	■ SSD-based guideline ■ EC_{10} preferred endpoint ■ Not normalized for hardness
	US EPA HC_5 method (Stubblefield et al. 2020)	7.1	■ SSD-based guideline ■ EC_{20} preferred endpoint ■ Not normalized for hardness
	BC ENV (1981)	4	■ Geometric mean of four LOEC values[c] (two for *Ceriodaphnia dubia*, two for *Daphnia magna*) of 8.2 µg/L divided by 2 (assessment factor) ■ Not normalized for hardness

Table 1-1: Overview of Generic Long-Term (Chronic) Water Quality Guidelines for Cobalt

Exposure Type	Guideline Agency	Guideline Value (µg/L)	Description of Guideline
Chronic	ANZECC (2000a)	1.4	■ Low reliability freshwater trigger value ■ Lowest chronic value in the freshwater dataset (four taxonomic groups) of 2.8 µg/L for *Daphnia magna* divided by 2 (assessment factor) ■ Not normalized for hardness

Notes: µg/L = micrograms per litre; BC ENV = British Columbia Ministry of Environment; NOEC = no observed effect concentration; LOEC = lowest observed effect concentration; ECCC = Environment and Climate Change Canada; EC_X = effective concentration causing X% reduction in sublethal endpoint; FEQG = federal environmental quality guideline; SSD = species sensitivity distribution; ANZECC = Australia and New Zealand Environment and Conservation Council.

[(a)] Guideline calculated based on a hardness of 61 mg/L as $CaCO_3$, which is the maximum predicted hardness at the edge of the mixing zone in Duley Lake under discharge condition.

[(b)] Calculated using the ECCC (2017) FEQG equation of exp{0.414×[ln(hardness)] – 1.887}.

[(c)] The LOEC values included the following: 12.5 µg/L (Golder/EVS chronic study, referenced in BC ENV [2004]) and 3.13 µg/L (Golder/BC Research chronic study, referenced in BC ENV [2004]) for *C. dubia* and 10 µg/L (Kimball, 1978) and 12 µg/L (Biesinger and Christensen, 1972) for *D. magna*.

For existing chronic cobalt guidelines, values range from 0.83 µg/L (using the ECCC [2017] hardness normalized equation[6] with EC_{10}s as the preferred endpoint), to 7.1 µg/L (using the US EPA-protocol final chronic species sensitivity distribution (SSD) based value with EC_{20}s as the preferred endpoint). The BC ENV (1981) and the Australia and New Zealand Environment and Conservation Council (ANZECC 2000a) chronic guidelines both included safety factors of two-fold from their original derived guidelines and were not normalized for hardness. Given the recency of the Stubblefield et al. (2020) report in terms of both updated toxicological data sets and Type A derivation approaches, such benchmarks are of interest for comparison to our site-specific water quality objectives (SSWQOs) derived below. Stubblefield et al. (2020) applied both the European Union protocol (EC_{10} preferred endpoint) and the US EPA protocol for final chronic SSD value (FCV; EC_{20} preferred endpoint); these HC_5 values from SSDs were retained as a check on the protectiveness of the SSWQO derived herein.

1-4 METHODS

The SSWQO, as described in the following section, was derived using the protocol outlined by the CCME (2007). This protocol has been applied by CCME for several other substances, including metals (aluminum, copper, iron, lead, selenium, and vanadium), providing a template for application to substances for which the scientific understanding of environmental toxicity has improved since the original CCME derivations. The CCME (2007) provides detailed procedures for deriving SSWQOs for the protection of aquatic life in Canada. A species sensitivity distribution (SSD) approach is used preferentially where the quantity and quality of available toxicity data are sufficient; otherwise, the lowest acceptable toxicity value approach is used.

[6] Guideline calculated using the ECCC (2017) federal environmental quality guideline (FEQG) equation and is based on a hardness of 61 mg/L as $CaCO_3$, which is the maximum predicted hardness at the edge of the mixing zone in Duley Lake under discharge condition.

1-4.1. Data Compilation

Effect concentrations were compiled and screened using the CCME (2007) guidance for Type A derivations, including definition of receptors and long-term test protocols suitable for inclusion, identification of preferred toxicological endpoints, and procedures for calculating species mean chronic values (SMCVs). Chronic toxicity data were compiled from a previous northern mining program, as well as species included in the ECCC (2017) FEQG. The organisms in the ECCC (2017) SSD were reviewed to assess whether each species was a resident, or could be considered a surrogate, for the fish, invertebrates, and aquatic plants found in the regional watercourses (receiving environment). An additional data search (2019 onward) was conducted using the US EPA ECOTOX Knowledgebase (US EPA 2020) and Google Scholar, and no additional studies meeting the search criteria were included.

1-4.1.1 Data Quality

Available studies were screened for inclusion or exclusion based on CCME (2007) guidance for developing the SSWQO. Test acceptability was confirmed by consulting the original publication or report and reviewing the test assessment methods. The applicable rules included the following:

- Studies evaluating effects to species that were not relevant to the site were excluded as follows:
  - tropical species were excluded
  - saltwater species were excluded
  - species were exclude if not ecologically relevant to the receiving environment of the Kami Iron Ore Mine complex due to poor representation of the regional taxonomic groups and/or functional roles in regional aquatic systems; retained organisms were intended to provide an appropriate representation of the biological community found at the site, but were not required to be documented as site residents.
    - Biological endpoints were selected for growth, reproduction, mortality, and development. Non-traditional endpoints (molecular markers, behaviour, swimming speed) were excluded per established guidance for ecological risk assessment (ECCC 2022).
    - Tests using field-collected organisms or performed in the field were excluded because of uncontrolled sources of variability (e.g., life history of organism unknown, exposure conditions not controlled, chemical mixtures present).
    - Studies with freshwater exposure to the substance in question were included. Experiments in which test organism exposure occurred through injections or diet were excluded.
    - Studies were excluded if exposure concentrations (e.g., nominal concentrations, extrapolated concentrations) or test duration were not reported.
    - Studies evaluating synergistic, or antagonistic effects of chemicals or compensatory responses of organisms (such as tolerance [acclimation, adaptation], or reduced density-dependent mortality among juveniles) were excluded.
    - Included studies must have followed good laboratory practices (e.g., presence of control group), a defensible experimental design, and accepted statistical procedures for data analysis.

1-4.1.2 Receptors

The minimum dataset requirements for the derivation of an SSD-based (i.e., Type A) long-term water quality guideline (WQG) for freshwater environments, as defined by the CCME (2007), are provided in Table 1-2. Toxicity data for amphibians are highly desirable, but not necessary, for a Type A SSD derivation (CCME 2007). As outlined CCME (2003), only site-relevant toxicological information should be used in the SSD generation. However, to maintain a robust dataset and not exclude potentially sensitive organisms, CCME (2003) outlines some guidance for site-relevance:

- If a member of a class of freshwater invertebrates occurs or could occur at a site (e.g., water flea from the family Hydropsychidae), then the toxicity data on any of the invertebrate species within that class can be included in the site-specific toxicological data set.
- If a member of a family of freshwater fish occurs or could occur at a site (e.g., rainbow trout from the family Salmonidae), then the toxicity data on any of the fish species within that family (e.g., rainbow trout, coho salmon, mountain whitefish, arctic grayling, arctic char) can be included in the site-specific toxicological data set.
- If a member of a phylum of freshwater algae occurs or could occur at a site (e.g., *Chlamydomonas debaryana* from the phylum Chlorophyta), then the toxicity data on any of the algal species within that phylum (e.g., *Chlamydomonas debaryana*) ca be included in the site-specific toxicological data set.

Table 1-2: Minimum Dataset Requirements for the Derivation of SSD-based Type A Guidelines

Receptor Group	Chronic SSWQO
Fish	Three fish species, including at least one salmonid and one non salmonid. Exposure periods involving juvenile or adult stages of at least 21 d in duration, or periods involving early life stages (eggs and larvae) of 7 d or more, are considered long-term exposures.
Aquatic Invertebrates	Three aquatic or semi aquatic invertebrates, at least one of which must be a planktonic crustacean. Long-term exposures are defined to include nonlethal endpoints from test durations of at least 96 h for shorter-lived invertebrates (e.g., *Ceriodaphnia dubia*), nonlethal endpoints of at least 7 d in duration for longer-lived invertebrates (e.g., crayfish), or lethal endpoints from tests of at least 21 d in duration for longer-lived invertebrates.
Aquatic Plants	At least one study on a freshwater vascular plant of freshwater algal species. Additional representation of macrophytes and algae is required for substances that have phytotoxicity as a dominant process. All tests for *Lemna* sp. following standard test protocols, as well as all tests with algae greater than 24 h, are considered long-term exposures.

Notes: d = days; h = hours; SSD = species sensitivity distribution; SSWQO = site-specific water quality objective.

1-4.1.3 Endpoints

For the development of long-term WQGs, CCME (2007) provides a preference ranking for selecting endpoints for a Type A guideline: most appropriate endpoint is an EC_X or IC_X representing a no-effects threshold > EC_{10}/IC_{10} > $EC_{11–25}/IC_{11–25}$ > MATC > NOEC > LOEC > $EC_{26–40}/IC_{26–49}$ > nonlethal EC_{50}/IC_{50} [7]. Following this hierarchy, “a threshold level for no negative effect is generally defined as an effect level of 10% or less of the exposed individuals of a species (i.e., EC_{10}), unless a more appropriate no effects threshold is defined for the test species

[7] EC_x = effective concentration causing x% reduction in sublethal endpoint; IC_x = the concentration that results in a magnitude of effect of x% over a specified period of time; MATC = maximum acceptable toxicant concentration (calculated as the geometric mean of the no observed effect concentration and lowest observed effect concentration); NOEC = no observed effect concentration; LOEC = lowest observed effect concentration.

in a generally accepted standardized test protocol" (CCME 2007). In practice, the most appropriate effect size used to define the EC_X or IC_X depends on the study design and test type, and sometimes entails professional judgement, including considerations of the statistical power of the toxicity study, statistical significance level, the type of biological endpoint under consideration, and the shape of the concentration-response curve.

For statistical endpoints, the preference ranking of the available data was conducted following guidance from CCME (2007) as described in the bullets above.

Decisions made by ECCC (2017) for the derivation of the FEQG, such as inclusion or exclusion of chronic toxicity data, selection of statistical endpoints (e.g., EC_{10} value versus EC_{20} value), and use of geometric means to calculate species mean chronic values, were evaluated. Several reports cited in ECCC (2017) could not be obtained (Parametrix 2010a,b,c; Heijerick 2007); however, the results from these studies were obtained from supplementary information reported in Stubblefield et al. (2020). Our approach followed the generic CCME (2007) preference for EC_{10} value versus EC_{20} value where the statistical power was adequate. However, in cases for which the EC_{10} value was below the no observable effect concentartion (NOEC), an alternate EC_X value was developed from the primary data. The endpoints selected are an appropriate balance between the considerations of effect size and statistical significance in the application of the CCME (2007) hierarchy for selection of a preferred statistical endpoint.

1-4.1.4 Hardness Normalization

Hardness was identified by ECCC (2017) as a key ETMF for cobalt. The hardness normalization for the SSD was conducted so that individual test results can be standardized for model fitting. Effect concentrations used to derive the SSD were normalized to a common test hardness (100 mg/L as calcium carbonate [$CaCO_3$]) except for tests conducted at hardness values less than 52 mg/L $CaCO_3$, which were normalized to a lower bound of 52 mg/L $CaCO_3$ (ECCC 2017). The decision to normalize tests conducted at hardness values less than 52 mg/L $CaCO_3$ to the lower bound of the calibration curve of 52 mg/L $CaCO_3$ was done in order to remain conservative, and reduce any uncertainty surrounding the overall hardness adjustment. Effect concentrations were normalized using the following equation from ECCC (2017):

$$EC_x\ (normalized\ hardness\ value) = 10^{(((0.414 \times (\log(normalized\ hardness\ value) - \log(original\ hardness)) + \log(original EC_x))}$$

Hardness-normalized effect concentrations were used to develop the SSD (Section 1-4.2).

1-4.1.5 Species Mean Chronic Values

Geometric means were used to calculate SMCVs where multiple effect concentrations were available for a particular species, provided that the test endpoints were comparable in terms of endpoint type, magnitude, and exposure conditions. Following CCME (2007) guidance, where multiple measurements reflect similar underlying toxicological endpoints, life stage, and approximate duration, it is appropriate to combine these effect concentrations using a geometric mean (i.e., effects concentrations are combined for comparable endpoint types and statistical endpoints). In some cases, professional judgment is required to distinguish comparable versus non-comparable endpoints. Guidance provided by Chapman (2015) was followed for cases where endpoint data were sufficiently similar in terms of endpoint type or magnitude to warrant aggregation using a geometric mean. As noted by Warne et al. (2016) in an update to the ANZECC (2000b) guidelines for fresh and marine water quality, "Chapman (2015) provides some excellent general guidance and seven rules regarding the calculation of geometric means."

1-4.2. Species Sensitivity Distribution

The BC ENV SSDtools package (Thorley and Schwarz 2018) in R (version 4.2.1; R Core Team 2022) was used to develop SSDs using the normalized species mean values. Per Schwarz and Tillman (2019), SSDs were fit using a maximum likelihood estimation with a model averaging approach. Models with a corrected Akaike information criterion (AIC) score within two (indicated by the delta) of the lowest AIC score, which indicates high empirical support (Fox et al. 2021), were retained for model averaging and weighted relative to their AIC scores. The "predict" function was used to generate a line of best fit and 95% confidence intervals, and the "SSD_hc" function was used to derive the HC_5. The 95% confidence intervals are generated using the bootstrap resampling method. As a result, confidence intervals will fluctuate due to stochasticity among SSD model runs using the BC ENV SSD tool and may differ slightly from what is presented in the SSD summary statistic table for applicable constituents.

The CCME (2007) recommends use of the HC_5 in Type A derivations, provided that the intended level of protection is fulfilled. Chronic HC_5 values are then evaluated to see if an additional protective measure, called the protection clause, should be invoked. As discussed in CCME (2007) the protection clause can be invoked if: 1) the derived HC_5 provides adequate protection of individual species of special concern; or 2) acceptable lethal effects endpoint (i.e., LC_X, where x ≥15%) for any species is lower than the proposed guideline. If either one of these occurs, or a species of heightened ecological or cultural interest fall below the HC_5, the lowest applicable endpoint concentration is applied as the guideline value. The "species of special concern" provision can be applied to both designated species (i.e., threatened or endangered resident species as defined under designation by the Committee on the Status of Endangered Wildlife in Canada or the *Species at Risk Act*) or to species that have high commercial, recreational, or ecological values (as determined on a case-specific basis).

The SMCVs were used to develop an SSD as described above, which was then used to derive the hardness-dependent SSWQO (Section 1-4.3).

1-4.3. Hardness-Dependent SSWQO Derivation

Given that water hardness decreases cobalt toxicity to freshwater aquatic organisms (ECCC 2017), the SSWQO is expressed as an equation into which the site-specific hardness is entered to produce an appropriate SSWQO. The SSWQO equation is based on the toxicity hardness-relationship (i.e., the slope 0.414 derived by ECCC [2017]) and the HC_5 value at 100 mg/L hardness (derived in the SSD section). The following equation was used to calculate the hardness-dependent SSWQO:

$$SSWQO\ (\mu g/L) = e^{\{0.414[\ln(hardness)]+\ y-intercept\}}$$

The y-intercept was calculated as follows (ECCC 2017):

$$y\ intercept\ = \ln(HC_5) - (hardness\ slope \times \ln(hardness))$$

$$y\ intercept\ = \ln(HC_5) - [0.414 \times \ln(100)]$$

where HC_5 is calculated from the SSD, slope is calculated in the hardness adjustment derived by ECCC (2017), and hardness is measured in $CaCO_3$ equivalents.

1-5 RESULTS

1-5.1 Data Compilation

The cobalt SSWQO was derived using a toxicity dataset representing chronic exposures. Chronic toxicity data compiled from a previous northern mining program were included, as well as species included in the ECCC (2017) guideline derivation. ECCC (2017) recently compiled, reviewed, and ranked chronic toxicity data for cobalt to generate an SSD that was standardized for hardness.

1-5.1.1 Receptors

The minimum dataset requirements for the derivation of an SSD-based (i.e., Type A) long-term WQG for freshwater environments were met for cobalt. Acceptable chronic toxicity data were identified for 13 species, including three fish species (*Brachydanio rerio*, *Pimephales promelas,* and *Oncorhynchus mykiss)*, six invertebrate species (*Hyalella azteca, Daphnia magna, Ceriodaphnia dubia, Lymnea stagnalis, Chironomus tentans,* and *Aeolosoma sp.*), and four aquatic plant/algae species (*Lemna minor, Raphidocelis subcapitata, Spirodela polyrhiza,* and *Chalmydomas reinhardtii*). These species were retained as surrogates for species expected to be found in the receiving environment, including Duley Lake.

Decisions made by ECCC (2017) regarding the inclusion or exclusion of chronic toxicity data were consistent with decisions made herein, except for those discussed in the following two subsections (Table 1-3).

Table 1-3: Comparison of Decisions Made by Environment and Climate Change Canada and WSP Regarding the Inclusion or Exclusion of Reliable Chronic Toxicity Data

Species	Endpoint	Toxicity Value (normalized) (µg/L)[a,b]	NOEC (normalized) (µg/L)[b]	Reference	ECCC Decision (2007)	WSP Decision
Zebrafish (*Brachydanio rerio*)	16 d EC_{10} (survival)	348 (348)	60 (60)	Dave and Xiu 1991	Include	Include
Zebrafish (*Brachydanio rerio*)	33 d EC_{10} (biomass)	1,085 (1,016)	1,020 (1,008)	Parametrix 2010a	Exclude	Exclude
Fathead minnow (*Pimephales promelas*)	34 d EC_{10} (survival)	351 (339)	210 (203)	Parametrix 2010c	Include	Include
Fathead minnow (*Pimephales promelas*)	28 d IC_{10} (growth)	480 (336)	NR	Kimball 1978	Exclude	Exclude
Rainbow trout (*Oncorhynchus mykiss*)	81 d EC_{10} (biomass)	2,171 (2,049)	2,200 (2,076)	Parametrix 2010a	Include	Use EC_{20} (EC_{10} < NOEC)
Amphipod (*Hyalella azteca)*	28 d IC_{10} (growth)	0.76 (0.7)	NR	Norwood et al. 2007	Include as geometric mean	Exclude (see rationale in text)
Amphipod (*Hyalella azteca*)	28 d EC_{10} (growth)	7.55 (6.88)	6.83 (6.2)	Heijerick et al. 2007		Include
Cladoceran (*Daphnia magna*)	21 d EC_{10} (reproduction)	32.4 (22.6)	60.8 (42.3)	Heijerick et al. 2007	Include	Use EC_{20} (EC_{10}<NOEC)
Cladoceran (*Ceriodaphnia dubia*)	7 d EC_{10} (reproduction)[c]	7.9 (7.7)	14 (13.6)	Parametrix 2010b	Include	Use EC_{20} (EC_{10}<NOEC)
Snail (*Lymnea stagnalis*)	28 d EC_{10} (growth)	9.61 (8.36)	26.1 (22.7)	Heijerick et al. 2007	Include	Use EC_{20} (EC_{10}<NOEC)
Midge (*Chironomus tentans*)	20 d EC_{10} (survival)	167 (202)	237 (28.6)	Pacific Ecorisk 2005	Include	Use EC_{20} (EC_{10}<NOEC)
Oligochaete (*Aeolosoma* sp.)	14 d EC_{10} (growth)	155 (200)	169.7 (219)	Parametrix 2010a	Include	Use EC_{20} (EC_{10}<NOEC)
Duckweed (*Lemna minor*)	7 d EC_{10} (growth)	4.9 (6.3)	8.8 (11.3)	Heijerick et al. 2007	Include	Include
Green algae (*Raphidocelis subcapitata*)	4 d EC_{10} (growth)	23 (31)	32.2 (43.6)	Heijerick et al. 2007	Include	Include

Table 1-3: Comparison of Decisions Made by Environment and Climate Change Canada and WSP Regarding the Inclusion or Exclusion of Reliable Chronic Toxicity Data

Species	Endpoint	Toxicity Value (normalized) (µg/L)[a,b]	NOEC (normalized) (µg/L)[b]	Reference	ECCC Decision (2007)	WSP Decision
Giant Duckweed (*Spirodela polyrhiza*)	4 d EC_{50} (growth)	140 (257)	NR	Gaur et al. 1994	Include	Include
Green algae (*Chlamydomonas reinhardtii*)	5 d EC_{30} (growth)	1,120 (2,055)	NR	Macfie et al. 1994	Include	Include

Notes: d = day; NOEC = no observed effect concentration; EC/IC_X = effective concentration causing X% reduction in sublethal endpoint; NR = not reported.

[a] Reliable chronic toxicity data are provided in Appendix D of ECCC 2017.

[b] Toxicity value and NOEC value reported in the original study. Values in brackets are the hardness-normalized effect concentration (obtained from Appendix D of Environment Canada [2017] or calculated based on normalization to 100 mg/L $CaCO_3$ except those values less than 52 mg/L $CaCO_3$, which were normalized to 52 mg/L $CaCO_3$ [*Chironomus tentans, Raphidocelis subcapitata, Spirodela polyrhiza* and *Chlamydomonas reinhardtii*]).

[c] ECCC FEQG (2017) incorrectly states SSD *Ceriodaphnia dubia* endpoint (EC_{10} = 7.7 µg/L) test duration as 21 d when it was confirmed to be a 7 d test (McTavish 2024; pers. comm.).

1-5.1.2 Statistical Endpoint Selection

For six species (five invertebrate and one fish), EC_{10} values selected by ECCC (2017) were below NOEC values measured in the same study. For these species, the next ranked appropriate EC_X value was selected, according to the CCME (2007) protocol hierarchy. The selected endpoints are an appropriate balance between the considerations of effect size and statistical significance in the application of the CCME (2007) hierarchy for selection of a preferred statistical endpoint. EC_{10} values for species *Lemna minor* and *Raphidocelis subcapitata* were also below the corresponding NOEC value; however, because EC_{20} values were not reported in Heijerick et al. (2007) and the original report could not be obtained, EC_{10} values were retained for inclusion in the SSD developed herein.

- *Daphnia magna*—Heijerick et al. (2007) reported a 21 d EC_{10} for *D. magna* reproduction of 32.4 µg/L, which is approximately two times lower than the NOEC (60.8 µg/L); therefore, the EC_{20} of 45.7 µg/L was selected, which falls below the NOEC.
- *Ceriodaphnia dubia*—Parametrix (2010b) reported a 7 d[h] EC_{10} for *C. dubia* reproduction of 7.9 µg/L, which is approximately two times lower than the NOEC (14 µg/L); therefore, the EC_{20} of 11.1 µg/L was used, which falls below the NOEC.
- *Lymnea stagnalis*—Heijerick et al. (2007) reported a 28 d EC_{10} for *L. stagnalis* of 9.61 µg/L, which is approximately three times lower than the NOEC (26.1 µg/L); therefore, the EC_{20} of 23.07 µg/L was used, which falls just below the NOEC.
- *Chironomus tentans*—Pacific Ecorisk (2005) reported a 20 d EC_{10} for *C. tentans* survival of 167 µg/L, which is approximately 1.5 times lower than the NOEC (237 µg/L). As a result, the EC_{20} of 225.2 µg/L was used, which falls just below the NOEC.
- *Aeolosoma* sp.—Parametrix (2010a) reported a 14 d EC_{10} for *Aeolsoma sp*. growth of 155 µg/L, which is slightly lower than the NOEC (169.7 µg/L); therefore, the EC_{20} of 185.4 µg/L was used, which falls just above the NOEC.
- *Oncorhynchus mykiss*—Parametrix (2010a) reported an 81 d EC_{10} for *O. mykiss* biomass of 2,171 µg/L, which is slightly lower than the NOEC (2,200 µg/L); therefore, the EC_{20} of 2,495 µg/L was used, which falls just above the NOEC.

Geometric Mean for *Hyalella azteca*

ECCC (2017) used a geometric mean for the *H. azteca* toxicity value included in the SSD. The geometric mean was calculated using the 28 d IC_{10} (growth) value from Norwood et al. (2007) (0.70 µg/L hardness normalized) and the 28 d IC_{10} (growth) value from Heijerick et al. (2007) (6.88 µg/L hardness normalized). Although the geometric mean was calculated using toxicity values for the same species, test duration, biological effect, and statistical endpoint, the two results differed by an order of magnitude. Following guidance from the European Chemical Agency (ECHA 2008a), the Norwood et al. (2007) and Heijerick et al. (2007) studies were reviewed in further detail to investigate potential reasons for the difference, and whether either result was an outlier warranting exclusion on the basis of non-representativeness or lack of validation (Chapman 2015).

[h] ECCC FEQG (2017) incorrectly states SSD *Ceriodaphnia dubia* endpoint (EC_{10} = 7.7 µg/L) test duration as 21 d when it was confirmed to be a 7 d test (McTavish 2024; pers. comm.).

- Our review indicates that the Norwood et al. (2007) study result is unreliable for several reasons. First, Norwood et al. (2007) observed considerable variation in growth at low and control concentrations of cobalt, which was acknowledged in the reliability evaluation conducted for this study[i]. For example, growth in the control treatment varied by a factor of three, ranging from approximately 0.5 to 1.7 mg/individual (Figure 3 of Norwood et al. 2007). This high background variation in clean water confounds the evaluation of cobalt response, especially for small effect sizes. The coefficient of variation for control growth was estimated to be 45%, which limits the reliability of statistical endpoints conducted in relation to control. The variation in growth at low and control concentrations is reflected in the wide confidence intervals on the IC_{25} estimate. The statistical endpoint reported by Norwood et al. (2007) was a 28 d growth IC_{25} of 2.87 µg/L (95% confidence: 0.63 to 13 µg/L). Second, the low effect concentration value adopted by ECCC (2017) is unreliable due to extrapolation well below the confidence limits of the IC_{25} estimate; ECCC used an IC_{10} estimate of 0.70 µg/L in the FEQG; this value was obtained from the original authors. ECCC (2017) did not report the confidence intervals on the IC_{10} estimate, but such would be extremely wide given the combination of both factors described above. Because the growth data were not tabulated or plotted against aqueous cobalt concentration in the paper, WSP was unable to calculate reliable or biologically meaningful effect concentrations (or confidence intervals) for varying effect sizes (e.g., IC_{10}). The recent Stubblefield et al. (2020) report also excluded this Norwood et al (2007) value in deriving their SSD-based chronic guidelines.
- The Heijerick et al. (2007) dataset produced an IC_{10} of 7.55 µg/L (95% confidence: 4.0 to 14.3 µg/L) (as reported in Stubblefield et al. 2020). This IC_{10} falls within the range of 28 d growth IC_{25} values from Norwood et al. (2007), with the difference in effect size being due to low power in the latter. The IC_{10} corrected to 100 mg/L hardness was 6.88 µg/L (ECCC 2017). Growth in the low and control treatments was less variable than observed in the Norwood et al. (2007) study, with the coefficient of variation being 7% in the control group.

Given the lower variability observed in the Heijerick et al. (2007) study, the IC_{10} estimate from this study (6.88 µg/L normalized to a hardness of 100 mg/L) was considered more reliable and was included as the chronic value for *H. azteca* herein.

1-5.1.3 Hardness Normalization

Following selection of statistical endpoints, the seven endpoints that differed from those calculated in the ECCC (2017) SSD were normalized to a common hardness (i.e., *Hyalella azteca*, *Ceriodaphnia dubia*, *Lymnea stagnalis*, *Daphnia magna*, *Aeolosoma sp.*, and *Oncorhynchus mykiss*). These six endpoints were normalized to a "ceiling value" of 100 mg/L $CaCO_3$ using the ECCC (2017) equation; tests for these organisms were conducted at hardness values greater than 100 mg/L $CaCO_3$, but incremental hardness amelioration above 100 mg/L $CaCO_3$ is uncertain (BC ENV 1981). The *Chironomus tentans* statistical endpoint was normalized to a "floor value" of 52 mg/L $CaCO_3$, as test hardness was 33 mg/L $CaCO_3$ (below 52 mg/L $CaCO_3$). The *Raphidocelis subcapitata, Chalmydomas reinhardtii,* and *Spirodela polyrhiza* endpoints were also normalized to 52 mg/L $CaCO_3$ as test hardness was below 52 mg/L $CaCO_3$, and remained identical to those included in the ECCC (2017) SSD. The remaining three endpoints remained identical to those included in the ECCC (2017) SSD were not recalculated (i.e., *Lemna minor*, *Pimephales promelas*, and *Brachydanio rerio*).

Chronic values used in the SSD derived herein are provided in Table 1-4.

[i] Robust study summaries available at: http://webnet.oecd.org/hpv/ui/handler.axd?id=5bb01961-770e-4a3d-9fcb-c70c9113326c

Table 1-4: Chronic Cobalt Toxicity Data Used for Species Sensitivity Distribution

Taxa Grouping	Species	Endpoint	Test Hardness	Toxicity Value (µg/L)	Normalized Toxicity Value[a] (µg/L)	Reference
Plant	Duckweed (*Lemna minor*)	7 d EC_{10} (growth)	55	4.9	6.3	Heijerick et al. 2007
Invertebrate	Amphipod (*Hyalella azteca*)	28 d EC_{20} (growth)[b]	125	7.55	6.9	Heijerick et al. 2007
Invertebrate	Water flea (*Ceriodaphnia dubia*)	7 d EC_{20} (reproduction)[b,c]	108	11.1	11	Parametrix 2010b
Invertebrate	Snail (*Lymnea stagnalis*)	28 d EC_{20} (growth)[b]	140	23.1	20	Heijerick et al. 2007
Plant	Green algae (*Raphidocelis subcapitata*)	4 d EC_{10} (growth)	25	23	31	Heijerick et al. 2007
Invertebrate	Water flea (*Daphnia magna*)	21 d EC_{20} (reproduction)[b]	240	45.7	32	Heijerick et al. 2007
Invertebrate	Oligochaete (*Aeolosoma sp.*)	14 d EC_{20} (growth)[b]	54	185	239	Parametrix 2010a
Plant	Giant Duckweed (*Spirodela polyrhiza*)	4 d EC_{50} (growth)	12	140	257	Gaur et al. 1994
Invertebrate	Midge (*Chironomus tentans*)	20 d EC_{20} (survival)[b]	33	225	272	Pacific Ecorisk 2005
Fish	Fathead minnow (*Pimephales promelas*)	35 d EC_{10} (survival)	109	351	339	Parametrix 2010c
Fish	Zebrafish (*Brachydanio rerio*)	16 d EC_{10} (survival)	100	348	348	Dave and Xiu 1991
Plant	Green algae (*Chalmydomas reinhardtii*)	5 d EC_{30} (growth)	12	1,120	2,055	Macfie et al. 1994
Fish	Rainbow trout (*Oncorhynchus mykiss*)	81 d EC_{20} (biomass)[b]	115	2,495	2,355	Parametrix 2010a

Notes: d = day; EC/IC_X = effective concentration causing X% reduction in sublethal endpoint; µg/L = micrograms per litre

[a] Chronic data ordered from smallest to largest normalized toxicity value.

[b] Endpoint differs from ECCC (2017) and hardness was calculated.

[c] ECCC FEQG (2017) incorrectly states SSD *Ceriodaphnia dubia* endpoint (EC_{10} = 7.7 µg/L) test duration as 21 d when it was confirmed to be a 7 d test (McTavish 2024; pers. comm.).

1-5.2 Species Sensitivity Distribution

The minimum dataset requirements were satisfied for the derivation of an SSD-based (i.e., Type A) SSWQO for freshwater environments as defined by CCME (2007). For Type A water quality derivations, CCME (2007) recommends use of the HC_5, provided that the derived HC_5 remains protective of species of special concern. The resulting HC_5 of 3.79 µg/L is presented in Table 1-5 and Figure 1-1, along with confidence limits and associated statistical output. The HC_5 for cobalt is lower than the lowest SMCV (6.3 µg/L for *L. minor*; Table 1-4), therefore, the protection clause was not triggered for cobalt.

Table 1-5: Chronic Cobalt Species Sensitivity Distribution Summary Statistics

Parameter	Distribution	95% LCL (µg/L)	95% UCL (µg/L)	Weighted Contribution to Overall HC_5 (µg/L)	Final HC_5 (µg/L)[a]
Cobalt	Gumbel	2.51	21.57	1.68	3.79 (1.0 –21)
	Log-logistic	0.52	19.10	0.53	
	Log-normal	0.84	21.68	1.35	
	Weibull	0.08	19.89	0.23	

Notes: HC_5 = hazardous concentration to 5% of the tested species, or the concentration that protects 95% of the tested species; LCL = lower confidence interval; UCL = upper confidence interval; µg/L = micrograms per litre.

[a] Final HC_5 is the sum of weighted HC_5 for the individual models with lower and upper confidence intervals presented in brackets.

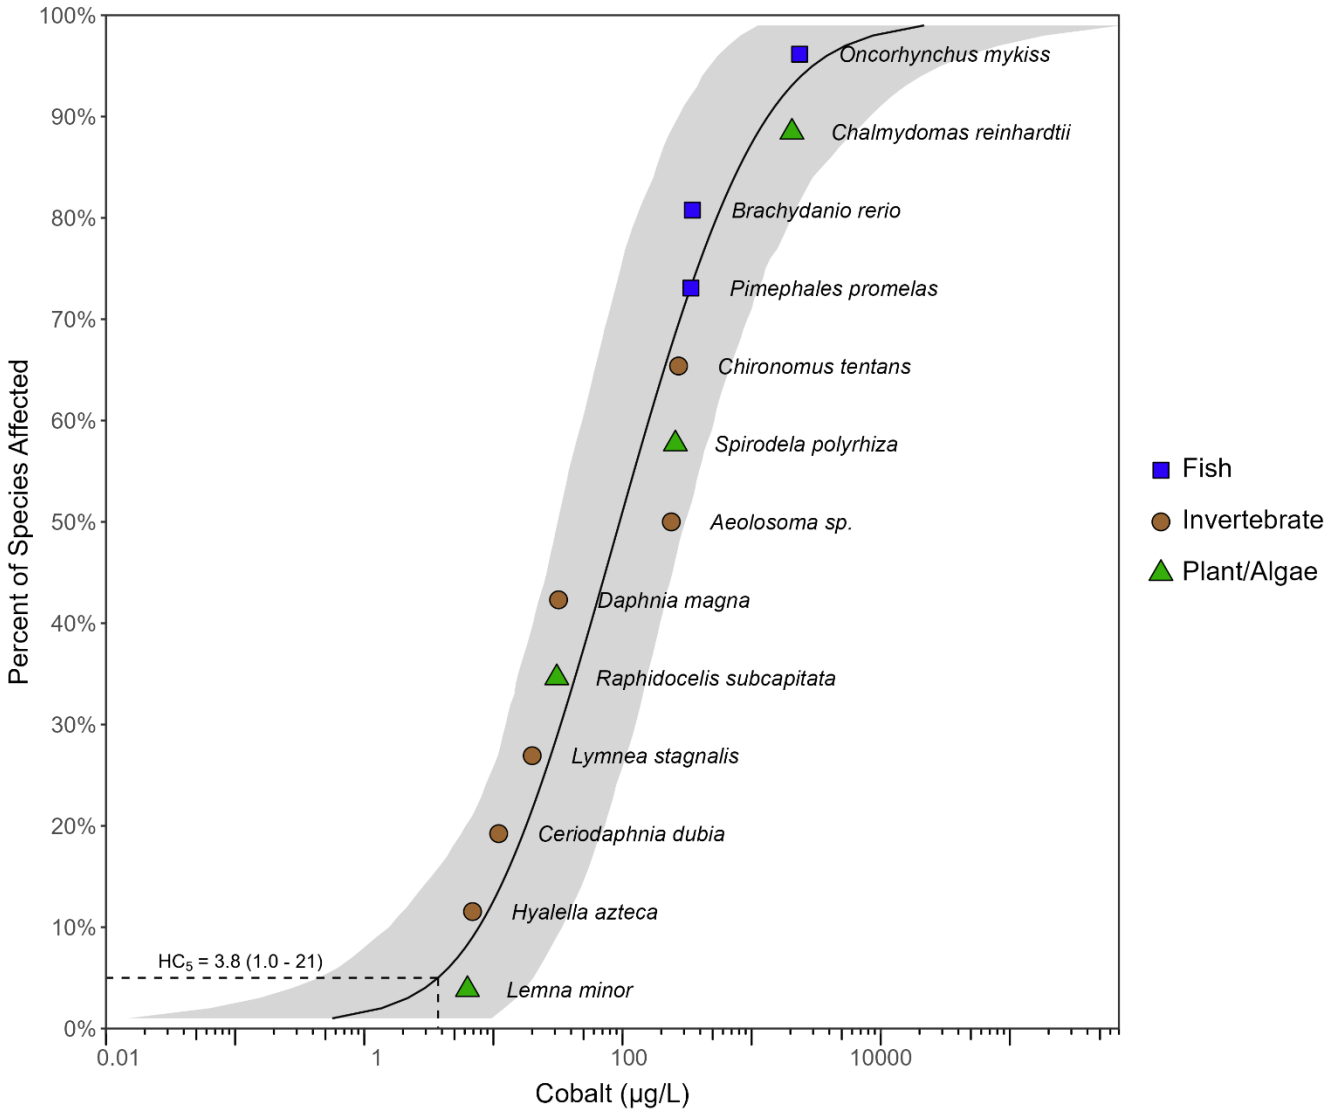

Figure 1-1: Species Sensitivity Distribution Curve for Chronic Cobalt Hardness-Normalized Toxicity Data

1-5.3 Proposed Hardness-Dependent SSWQO

The long-term cobalt SSWQO equation is based on the procedure used in ECCC (2017). Because water hardness decreases cobalt toxicity to freshwater aquatic organisms (ECCC 2017), the SSWQO is to be expressed as an equation into which the site-specific hardness must be entered in a forward calculation to produce an appropriate SSWQO. The SSWQO equation is based on the toxicity hardness-relationship (i.e., the slope 0.414 derived by ECCC [2017]) and the HC_5 value at 100 mg/L hardness of 3.79 (derived in the SSD Section 1-5.2). The following equation was used to calculate the hardness-dependent SSWQO:

$$SSWQO\ (\mu g/L) = e^{\{0.414[\ln(hardness)]+\ y-intercept\}}$$

The y-intercept was calculated as follows (ECCC 2017):

$$y\ intercept\ = \ln(HC_5) - (hardness\ slope \times \ln(hardness))$$

$$y\ intercept\ = \ln(3.79) - [0.414 \times \ln(100)]$$

$$y\ intercept\ = -0.57417$$

where HC_5 is calculated from the SSD, slope is calculated in the hardness adjustment, ln is the natural logarithm function, and hardness is measured in $CaCO_3$ equivalents.

Using the calculations outlined above, the final hardness-dependent SSWQO equation is:

$$SSWQO\ (\mu g/L) = e^{\{0.414[\ln(hardness)]-\ 0.57417\}}$$

As stated in ECCC (2017) this long-term SSWQO was calculated over a hardness range of 52 to 396 mg/L as $CaCO_3$, which corresponds to the hardness range over which the pooled slope value of 0.414 was used by ECCC (2017). The above equation and predicted hardness conditions were used to generate SSWQO values for low flow (25th percentile annual precipitation [P25]), high flow (75th percentile annual precipitation [P75]), and average flow (mean annual precipitation [MAP]) during construction, operations, closure, and post-closure at the both Duley (Table 1-6 and Figure 1-2) and Pike Lake (Table 1-7 and Figure 1-3). Site projections of water hardness ranged from 46 to 61 mg/L as $CaCO_3$, which is marginally outside of the bounds for which ECCC derived the pooled slope value of 0.414. This minor difference does not affect the reliability of the ECCC (2017) hardness adjustment that was applied to derive SSWQO values for the three flow scenarios (P25, MAP, P75) and the four project phases (construction, operations, closure, and post-closure).

SSWQOs were similar among scenarios and phases, ranging from 2.7 to 3.2 µg/L, whereas the maximum predicted total cobalt concentrations were ≤2.34 µg/L across all modelled precipitation years and project phases for both Duley (Table 1-6 and Figure 1-2) and Pike Lake (Table 1-7 and Figure 1-3). The resulting hardness-normalized HC_5 of 3.79 µg/L, and the corresponding long-term hardness-dependent cobalt SSWQO equation, are protective of aquatic life in the receiving environment, and appears to be suitable for the Kami Iron Ore Mine Project.

Stubblefield et al. (2020) recently derived chronic (non-normalized) guidelines using both the European-based SSD approach (EC_{10} preferred endpoint) or the US EPA-style final chronic SSD value (FCV; EC_{20} preferred endpoint); these derivations yielded HC_5 values of 1.8 µg/L and 7.1 µg/L, respectively. The hardness-normalized HC_5 of 3.79 µg/L (using a blend of EC_{10} and EC_{20} values) is intermediate between these two values. This independent confirmation of our derivation provides additional confidence in its protectiveness.

Table 1-6: Summary Statistics and Output for Cobalt for Low, Average, and High Flow Projections during Construction, Operational, Closure, and Post-Closure Phases at Duley Lake

Project Phase	Duley Lake								
	Low Flow (P25)			Average Flow (MAP)			High Flow (P75)		
	Hardness (mg/L as $CaCO_3$)[a,b]	SSWQO (µg/L)	Maximum Cobalt (µg/L)[b]	Hardness (mg/L as $CaCO_3$)[a,b]	SSWQO (µg/L)	Maximum Cobalt (µg/L)[b]	Hardness (mg/L as $CaCO_3$)[a,b]	SSWQO (µg/L)	Maximum Cobalt (µg/L)[b]
Construction	49.3	2.83	0.19	49.3	2.83	0.19	49.4	2.83	0.19
Operational	54.7	2.95	2.34	53.3	2.92	2.11	53.1	2.92	1.93
Closure	47.7	2.79	2.03	47.3	2.78	1.68	47.2	2.78	1.49
Post Closure	47.8	2.79	0.14	47.3	2.78	0.14	47.3	2.78	0.13

Notes: mg/L = milligram per litre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate.
