Hydrogeological Modelling Report
Our file: 692696-7000-4WER-0001_01

Dear sir Groleau,

We are pleased to submit the final version of the report mentioned in the above subject.
Do not hesitate to communicate with the undersigned should you have further questions regarding the content of this report.

Truly yours,

ATKINSRÉALIS INC.

Marie-Hélène Paquette, Eng.

Notice to Reader

This report has been prepared and the work referred to in this report has been undertaken by AtkinsRéalis Canada Inc. (AtkinsRéalis), for the exclusive use of Minerai de Fer Québec, who has been party to the development of the scope of work and understands its limitations. The methodology, findings, conclusions and recommendations in this report are based solely upon the scope of work and subject to the time and budgetary considerations described in the proposal and/or contract pursuant to which this report was issued. Any use, reliance on, or decision made by a third party based on this report is the sole responsibility of such third party. AtkinsRéalis accepts no liability or responsibility for any damages that may be suffered or incurred by any third party as a result of the use of, reliance on, or any decision made based on this report.

The findings, conclusions and recommendations in this report (i) have been developed in a manner consistent with the level of skill normally exercised by professionals currently practicing under similar conditions in the area, and (ii) reflect AtkinsRéalis' best judgment based on information available at the time of preparation of this report. No other warranties, either expressed or implied, are made with respect to the professional services provided to Minerai de Fer Québec or the findings, conclusions and recommendations contained in this report. The findings and conclusions contained in this report are valid only as of the date of this report and may be based, in part, upon information provided by others. If any of the information is inaccurate, new information is discovered or project parameters change, modifications to this report may be necessary.

This report must be read as a whole, as sections taken out of context may be misleading. If discrepancies occur between the preliminary (draft) and final version of this report, it is the final version that takes precedence. Nothing in this report is intended to constitute or provide a legal opinion.

The contents of this report are confidential and proprietary. Other than by Minerai de Fer Québec, copying or distribution of this report or use of or reliance on the information contained herein, in whole or in part, is not permitted without the express written permission of Minerai de Fer Québec and AtkinsRéalis.

1. Introduction

1.1 Context

Champion Iron Mines Ltd (Champion), is proposing to construct and operate the Kami Iron Ore Project (the "Kami Project"), which will involve the construction, operation and eventual closure of an iron ore open pit mine and the supporting infrastructure. The mine operation is expected to produce 8 million tonnes of iron ore concentrate annually, which will be transported by rail to the Pointe Noire port terminal in Ville de Sept-Îles, Québec, for international shipping.

The Kami Project includes construction, operation, and closure/decommissioning and post closure of the following primary components:

- The open pit mine (the Rose Pit).
- The Overburden Stockpile and Mine Rock Stockpile.
- The processing infrastructures including crushing, grinding, spiral concentration, magnetic separation, and tailings thickening areas.
- The Tailings Management Facility (TMF).
- The ancillary infrastructure to support the mine and process plant.
- A rail transportation component including spur line construction to connect the mine site to the Québec North Shore & Labrador Railway (QNS&L).

The project was previously developed by Alderon in 2010 – 2012 and an Environmental Impact Statement was submitted to the government of Newfoundland & Labrador (N.L.) in October 2012. It was approved by the latter in January 2014. In 2018, the Feasibility Study of the project was updated by Alderon. Champion Iron is the new owner of the Kami asset and wishes to update the Feasibility Study and to resubmit the project for approval by the government of N.L. The overall Feasibility Study is led by BBA.

Compared to the water management philosophy presented by Alderon in 2012, improvements were made to the Feasibility Study in order to comply with the conditions requested by the N.L. government as part of the 2014 project release. Refining the hydrogeological knowledge of the project is the main 2014 condition affecting the water management plan.

The main uncertainty related to water management in the Kami Project is the amount of groundwater infiltration associated with the development of Rose Pit. Due to the geology of the area and the poor quality of the bedrock, a large amount of infiltration is expected in the pit.

A review of project data, new site investigations and the creation of an updated conceptual hydrogeological model incorporating a better understanding of the site were carried out with the objective of reducing the risks associated with pit dewatering while complying with the 2014 N.L. government project conditions. The completion of these tasks has improved the hydrogeological understanding of the site and will allow Champion to plan for the large water infiltration volumes expected during dewatering operations.

1.2 Mandate

As part of the Pre-Feasibility Study update and following the conditions of the 2014 government approval, Champion has mandated AtkinsRéalis Inc. (AtkinsRéalis) to conduct a hydrogeological study. The hydrogeological study is an input to the infrastructure design, and includes:

- Data revision and data gap analysis (completed Q2 2023);
- Hydrogeological conceptual modelling of the site, including geological interpretation of the faults;
- Numerical model construction;
- Estimation of open pit dewatering rate;
- Planning of the field work necessary to fill the data gaps.

A detailed hydrogeological model will be prepared in the next phase of engineering, following the field work, which has been completed in Q3 2023 and will resume in the next phase of engineering.

2. Conceptual Model

2.1 Site Location and Proposed Infrastructures

The proposed Kamistiatusset Iron Ore Mine Project (Kami Project) is located in the general vicinity of the towns of Wabush and Labrador City (Labrador), approximately 5 km northeast of the town of Fermont, along the Québec-Labrador border (Figure B1).

The Kami Project is situated in a hilly terrain, marked by lakes and valleys with a northeast-southwest orientation. Topography across the site is generally governed by the underlying geological structures with elevations ranging from 594 m to 700 m (Stantec, 2012a).

The pit footprint will be centered on the valley south of Pike Lake and will extend over the topographic highs to the west (680 m), towards Gleeson Lake and to the east (665 m), north of Molar Lake. To the east and west, the pit will be surrounded by Mills and Daviault lakes respectively. The surface area of the pit footprint will be of approximately 2.80 km^2, with an overall perimeter of 8 km. The maximum pit depth will extend to approximately 450 m below the existing grade.

In addition to the pit, the site will also include the Overburden Stockpile, the Mine Rock Stockpile, the Tailings Management Facility (TMF), a Railway line and processing infrastructures.

2.2 Geology

2.2.1 Overburden

Overburden materials consist of veneers of organic soils (peat) overlying sequences of glacial till, and occasional glacio-fluvial and fluvial deposits overlying bedrock (Stantec, 2012a). The overburden in the Rose Pit area is generally described as a thin layer of organic topsoil or peat, overlying loose to compact brown silty sand glacial till with cobbles and boulders, becoming denser with depth (Stantec, 2012a). The interface with the bedrock sometimes exhibits sand and gravel, possibly highly weathered bedrock in some boreholes (Stantec, 2012a).

Around Rose Pit, the ROB-series boreholes, 22 boreholes drilled by Stantec in 2011, provide detailed overburden stratigraphy, with most of them reaching the first few metres of bedrock. Geotechnical logs are provided in Appendix C. In the pit footprint, exploration boreholes (K-series) also provide information on overburden thickness, but not detailed stratigraphy.

Based on the ROB and K-series boreholes, the overburden in the vicinity of the Rose Pit exhibits a highly variable range in thickness and a complex bedrock surface topography. In general, glacial till thicknesses range from 0.9 (K-10-52) to 62.2 m (K-11-108), with an average of 21.6 m. The maximal thickness encountered in the ROB-series boreholes is 52.4 m at ROB-11-07. The center of the valley, marked by an alignment northeast-southwest of small lakes, is formed by a depression in the bedrock where the till thickness is greater.

Outside the pit area, south of Long Lake, geotechnical investigations conducted by Stantec in 2012 confirm the presence of a topsoil layer underlain by till deposits. Depending on topography, till thickness is also variable in this area, and ranges from 0.2 to 48.4 m, at BH-12-42 and BH-GE-11 respectively.

An interpolation of the till thickness at the study area is provided in Figure B2. In the pit and tailings area, the interpolation is based on data from exploration and geotechnical drilling. Outside this area, on the periphery of the study zone, control points were added to fill the data gaps: estimated thickness ranges between 1 and 5 m on the topographic highs and is approximately 20 m in the valleys.

2.2.2 Regional Bedrock Geology

The rocks of the Kami Project property form part of the highly metamorphosed and deformed metasedimentary sequence in the Grenville Province of the Labrador Trough (Stantec, 2012a). The bedrock geology consists of folded, metamorphosed sequences of the Ferriman Group, overlying Archean aged basement rock (**Figure 2-1**). A regional geological map of the area is presented in Figure B3.

FERRIMAN GROUP	Dykes/Sills	Intrusive sediment-sill complex into Menihek Fm mud, essentially syndepositional
	- intrusive contact -

Figure 2-1: Kami Project Property Stratigraphy (Stantec, 2012a) from Clark and Wares' (2006) Nomenclature

2.2.3 Rose Pit Bedrock Geology

As presented in Figure B4, in the pit area, bedrock information is available from exploration boreholes (K-series) and shallow geotechnical boreholes (ROB-series). The maximum vertical depth of ROB-series boreholes is 60 m at ROB-11-07 (mainly in overburden), while that of K-series is around 500 m, at K-11-161.

2.2.3.1 Shallow Bedrock

Based on RBR-12-01, RBR-12-02 and the 18 ROB-series boreholes reaching the bedrock (typically 3 to 4 m of core), the shallow bedrock zone can range from a highly competent (based on Rock Quality Designation – RQD) to a highly weathered and fractured material with minimal core recovery (RQD = 0). Strong to very strong rock conditions (with likely poor permeability) were noted at ROB-11-06, 10, 11, 12, 17 and 20; poor rock conditions consistent with highly weathered or severely fractured conditions (and possible moderate permeability) were noted at ROB-11-03, 07, 08, 09, 18, 19 and RBR-12-01 and 02. Moderately strong to slightly fractured conditions are noted at ROB-11-01, 02, 04, 05, 13, 14, 15 and 16. The borehole logs presenting the measured RQDs are presented in Appendix C.

2.2.3.2 Structural Geology

A recent re-evaluation and analysis of geological data and exploration logs have helped refine the structural understanding of the rock formations encountered at the Kami Project deposit, leading to the creation of a 3D geological Leapfrog model (GMining, 2023).

The various formations identified are presented in Figure B4. From the deepest to the shallowest, the sequence consists of Archean gneiss (Katsao formation), dolomitic marble (Denault formation), quartzite sandstone (Wishart formation), iron formations (Sokoman formation) and mica schist (Menihek formation). The Rose Central and Rose North deposits represent a northeast-southwest trending anticline and syncline, respectively, juxtaposed by thrusting from the southeast. The folds are overturned and generally steeply inclined, dipping towards the southeast.

The Rose Central anticline gently plunges towards the northeast and closes at the approximate eastern extent of the proposed Rose Pit (Stantec, 2012a).

To the east of the pit, the core of the anticline is composed of the Denault and Wishart formations. To the west of the pit, the syncline is mainly composed of the Katsao, Wishart and Sokoman formations. The core of the syncline has not been identified due to the absence of boreholes having crossed this structure, but it is thought to be in the Menihek formation. In general, the formations dip to the southeast at an angle of 75° and a strike of 135° (Stantec, 2012a). Two NW-SE sections, perpendicular to the formations, show the geological sequence at depth near RBR-12-01 and RBR-12-02 (Figure B5).

2.2.3.3 Katsao-Wishart Fault

The stability analysis carried out by Stantec in 2012a provided an initial characterization of the rock formation quality, subdividing the pit into four (4) main areas or rockmass domains: NR1 and NR2 to the west, and RC1 and RC2 to the east. Generally, the bedrock in the eastern part of the pit is of good quality, while that in the western part is of good to poor quality, with deep and intense weathering. The most significant area of weathering was noted at NR2 (Stantec, 2012a). In this zone, the entire Wishart was observed in some boreholes to be weathered to poorly consolidated sand. The intense fracturing and alteration of the Wishart is linked to the presence of a major fault interpreted on a regional scale and formed by the contact between the Katsao and Wishart formations. The Katsao-Wishart fault is illustrated at a regional scale on Figure B3 and in the pit area on Figure B4.

In terms of groundwater flow, it appears that the entire Wishart Formation could be considered as a water-bearing structure with an average width of 50 m (Figure B5).

2.2.3.4 Central Fault

An analysis of televiewers surveys from 2008 to 2012 is presented in Appendix D. For each selected borehole, potential fault intervals were identified based on the general bedrock quality and fracture type. Drillcore photos (Appendix E), taken during 2 site visits (May and July 2023), were also analyzed to identify potential fault zones. This analysis led to the identification of several potential fault intervals within the pit area. These highly fractured and altered zones feature pulverized rock horizons of varying thicknesses (between 20 and 50 m) and are mainly found within the Sokoman formation, in the central part of the pit. These intervals occur at different depths (between 150 and 350 m along the borehole depth) but do not appear to be related to changes in stratigraphy.

To identify a potential 3D fault plane, fractured intervals were mapped into the Leapfrog model. However, the spatial distribution of data did not allow to locate a precise fault plane. However, it appeared that the major fracture zones had a similar orientation with a 75° dip to the southeast. These fracture zones could be related to the development of the iron deposit and the upwelling of hydrothermal fluids as suggested by intervals of vuggy bedrock on core samples (**Figure 2-2**).

Figure 2-2: Vuggy Bedrock Located at Around 430 m in the Sokoman Formation (KGT-23-03)

For simplification, these major fracture zones, within the Sokoman, in the center of the pit, will be referred to as the "Central fault" for the remainder of the study. The approximate location of the Central fault is shown on Figures B3, B4 and B5. The true thickness of these fractures has been interpreted between 20 and 40 m, based on boreholes analyses at RBR-12-02, K-12-176A and K-12-179. In terms of groundwater flow, the central fault could be considered as a water-bearing structure with an average width of 30 m.

2.2.3.5 Other Potential Faults

Stantec's Pit Slope Design report (2012a) mentions the presence of a potential fault in the Menihek unit (syncline axis). However, deep exploration holes have not encountered the closure of the syncline and the existence or location of this fault was not confirmed to date.

Interpreted sub-vertical dip-slip faults bisect the deposits, trending roughly northwest-southeast. Three of these major features have been interpreted by Alderon and are illustrated on Figures B3 and B4; however, it is understood that more structures may be present based on reviews of aerial imagery. As a result of directional bias of the exploration boreholes, these structures are rarely intersected and are currently only interpreted through 3D geological interpolation (Stantec, 2012a).

2.3 Climate and Hydrology

In general, the area of West Labrador experiences sub-arctic climatic conditions characterized by long cold winters and short mild summers. Based on data obtained from the Wabush Lake A station for the period of 1961-2012 (Environment Canada, 2023), a large variation in mean daily temperatures is observed throughout the year, from -22.0 °C in January to 13.8 °C in July, with a mean annual daily temperature of -3.2 °C (SNCL, 2023).

Annual precipitation averages 878.1 mm/year with a range of 675.8 (100-years Dry) to 1265.1 mm/year (100-years Wet) (SNCL, 2023), while annual evapotranspiration averages 387.3 mm/yr (SNCL,2023). Freezing conditions typically occur between mid-October and early November, and major snow melt typically occurs between late April and mid-June. The Kami Project property is in an area of “isolated patches of permafrost” according to Natural Resources Canada (NRC, 1993) and although no permafrost zones were encountered during the field work carried out by Stantec in 2012, several wells were reported to be frozen during groundwater level surveys:

- ROB-11-18 was frozen in November 2011 (Stantec, 2012a);
- ROB-11-01A/B were frozen in April 2012 (Stantec, 2012b);
- K-11-113, K-11-147 and ROB-11-08 were frozen in March 2012 (Stantec, 2012b).

2.4 Lakes Water Elevation

The major lakes in the study area and their water elevations are shown in **Table 2-1**. At the time of this study, all measured lake water levels were not available, so an estimate was made using topographic contours from lidar or the government digital elevation model (DEM). It is also worth noting that the bathymetry of the lakes was not available at the time of the study.

Table 2-1: Estimated Lake Water Level Around Rose Pit Area Based on Topographic Data

Lake	Lake Water Level Elevation (m)	
	Based on closest topographic line (Lidar 1 m interval)	Based on closest topographic line (DEM 10 m interval)
Pike	568	-
Molar	-	594
Long	538	-
Mills	579	-
Daviault	-	594
Riordan	588	-

A regional map of natural watershed is available in SNCL, 2023. Drainage generally occurs to the northeast. More locally, Pike Lake receives surface water from the Rose Pit area and ultimately discharges into Long Lake. Because of its proximity to the pit, Pike Lake is at risk of a reduction in water level due to the dewatering operations of Rose Pit. The potential drawdown at Pike Lake will depend on the following elements:

- Hydraulic gradient between the lake and the pit;
- The presence of high hydraulic conductivity structures, such as faults or fractures, connecting the pit and the lake;
- Thickness and hydraulic conductivity of lake-bottom sediments and/or overburden under the lake;
- Thickness and hydraulic conductivity of the overburden between Pike Lake and the Rose Pit;
- Lake recharge rate (natural or anthropogenic).

For a conservative approach to dewatering flows rate estimation, it was assumed that the level of the lakes in **Table 2-1** would remain stable during the Rose Pit dewatering. Indeed, some lakes (including Pike Lake) could serve as receptors for dewatering water – if quality criteria are met.

2.5 Hydrogeological Context

2.5.1 Groundwater Levels

Figure B6 shows the location of the 32 wells monitored during fieldwork carried out by Stantec in 2012a. The wells are distributed across the entire proposed pit area, with well screens intercepting till, till/bedrock and bedrock. ROB wells account for most of the wells installed on site (24 wells), mainly in the till and occasionally in the superficial bedrock. Eight exploration boreholes complete the piezometric data from the bedrock aquifer. **Table 2-2** shows the static groundwater levels measured between November 2011 and June 2012. To monitor temporal variations in groundwater levels, pressure transducers were also installed in 11 of these wells, between December 2011 and April 2012. The hydrographs of the pressure transducer data (December 2011 to April 2012) are presented in Appendix F with additional monthly hydrographs. These hydrographs show a general decreasing trend in water levels over the course of the winter when frozen ground conditions and snow cover limit the groundwater recharge (Stantec, 2012a).

Groundwater levels in the Rose Pit area closely correlate with topography and range from 11.64 mbgs in areas of high elevation (ROB-11-06, western part of the pit) to artesian conditions in areas of low elevation (**Table 2-2**). Topographic highs to the west (near Gleeson Lake) and south-east of the pit (North of Elfie Lake) act as preferential recharge areas (grey zones, Figure B6). In contrast, the center of the valley represents a local discharge area (orange zone, Figure B6) where an alignment of lakes such as Mid, Rose and Pike lakes is formed. The relative elevations range from 647 masl at ROB-11-06, in the topographic high to the west, to a low of 578.1 masl at ROB-11-17 in the bottom of the valley; thus creating a water-level difference of 69 m within a relatively small distance (850 m). These high relative elevations account for the numerous flowing artesian wells in the lower areas of the site (Stantec, 2012a). Indeed, during field investigations carried out by AtkinsRéalis in May and September 2023, some wells and exploration boreholes showed artesian conditions. The locations of these wells are presented in Figure B6. Pressure transducers were also installed to confirm water level variations within the pit area, but the data has yet to be analyzed since the associated fieldwork is still ongoing.

The general groundwater flow follows the hydrographic drainage and flows towards Pike Lake. A piezometric map of the Rose Pit area, based on 2012 measurements (**Table 2-2**), is presented in Figure B6. Given the lack of data for each aquifer (bedrock and till), all available measurements were considered to create the piezometric map.

Table 2-2: 2011-2012 Measured Groundwater Levels in the Pit Area

Well ID	Borehole Data							Measured Groundwater Levels (mbgs)							Logger Data

2.5.2 Groundwater Gradients

Horizontal gradients were estimated between different pairs of wells, in the till/bedrock or the bedrock. Strong gradients are seen on slopes, in the bedrock, between K-08-10 and K-08-18 (0.08 m/m) and ROB-11-05A and K-11-113 (0.17 m/m). More gentle gradients were estimated in the center of the valley, at the till/bedrock interface, between ROB-11-07 and ROB-11-02 (0.02 m/m) and between ROB-11-04 and ROB-11-02 (0.03 m/m). The **Table 2-3** presents the detailed calculation of horizontal gradients in the pit area.

Table 2-3: Horizontal Groundwater Gradients Estimated in the Pit Area

ID	Screened Unit	Mean Measured Groundwater Elevation (m)	Groundwater Elevation Difference (m)	Distance (m)	Horizontal Gradient i_h (m/m)	Groundwater Flow Direction
ROB-11-07	till/bedrock	596.92	28.32	1760	0.02	SW-NE towards Pike Lake
ROB-11-02	till/bedrock	568.6				
ROB-11-04	till/bedrock	594.98	26.38	775	0.03	Easterly towards Pike Lake
ROB-11-02	till/bedrock	568.6				
K-08-10	bedrock	627.6	44.43	550	0.08	Northerly towards Pike Lake
K-08-18	bedrock	583.17				
ROB-11-05A	bedrock	625.56	42.51	250	0.17	NE-SE towards Rose Lake
K-11-113	bedrock	583.05				

The presence of multi-level wells, ROB-11-01A/B, ROB-11-05A/B, ROB-11-08A/B and ROB-11-13A/B provides an opportunity to estimate local vertical gradients. The following observations were made:

- Due to artesian conditions, water levels were not precisely measured at ROB-11-01A/B;
- A vertical downwards gradient of 0.06 m/m was estimated at ROB-11-05A/B, in the western part of the pit, on a topographic high;
- Vertical upwards gradients were estimated at ROB-11-08A/B (0.17 m/m) in the local discharge area in the valley center;
- Vertical upwards gradients were also estimated at ROB-11-13A/B (0.04 m/m) located on a topographic high in the eastern part of the pit. Stantec (2012a) mentioned that the upward gradient at ROB-11-13A/B in an upland area is attributed to shallow bedrock, which may be locally confined by the overburden.

The Table 2-4 presents the detailed calculation of vertical gradients in the pit area.

Table 2-4: Vertical Groundwater Gradients Estimated in the Pit Area

ID	Measured Groundwater Levels (mbgs)			Groundwater Elevation Difference	Mid Screen Distance	Vertical Gradient i_v	Groundwater Flow Direction
	A	B	Date	(m)	(m)	(m/m)	
ROB-11-05	2.12	1.57	Jun. 2012	0.55	8.9	0.06	Downwards
ROB-11-08	-1.45	0.58	Jan. 2012	-2.03	11.15	0.18	Upwards
ROB-11-13	5.09	5.37	Apr. 2012	-0.28	7.65	0.04	Upwards

2.5.3 Groundwater Recharge

As mentioned in previous sections, recharge areas are mainly observed in topographic highs and discharge zones in topographic lows, where artesian conditions have been observed. Groundwater recharge at Rose Pit can be roughly estimated based on the water balance, as follows:

Recharge = Total Precipitations – Evapotranspiration – Runoff

Considering annual precipitation for a dry or wet year, recharge is estimated between 0 and 130 mm/year, with:

- Total precipitation (SNCL, 2023) = between 675.8 and 1265.1 mm/year;
- Rose Pit runoff coefficient for summer/fall (SNCL, 2023) = 0.59;
- Evapotranspiration (SNCL, 2023) = 387 mm/year.

2.5.4 Groundwater Quality

In 2012, the groundwater quality in the Rose Pit area was characterized from 15 wells and boreholes. A more detailed interpretation can be found in Stantec, 2012a. Analysis of groundwater geochemistry is an important component of hydrogeological modelling, providing a better understanding of the conceptual model. A preliminary assessment of groundwater chemistry is also required to evaluate the potential effects of mine-related seepages, and the potential for the on-site development of water supply wells. Differentiation between the geochemical signature of groundwater and surface water could also help interpret water inflows during dewatering.

Based on the elevations of the saturated sand packs, 7 wells were screened across the till/bedrock interface (ROB-11-5A, 02, 10, 11, 12, 13A, 17 and 20), 3 wells were completed within the glacial till (ROB-11-5B, 8B and 13B), and 4 wells were installed in the fractured bedrock units (ROB-11-8A and boreholes K-11-108, 113 and 163).

The major ion concentrations of all 14 sampled wells were similar, and generally described as a clear to slightly coloured, moderately soft (average hardness 62.3 mg/L), neutral to slightly acidic (average alkalinity 72.4 mg/L, average pH 7.9, average calcite saturation index -0.7 at 4 degrees Celsius), calcium-bicarbonate water type of low TDS (average 95.5 mg/L). Chloride is notably low (average 1.3 mg/L; maximum 5.4 mg/L) in these groundwater samples.

Groundwater quality was analyzed for the till, the till/bedrock, and the bedrock:

- In the till, all parameters except manganese (average concentration of 297 µg/L) meet GCDWQ (Guidelines for Canadian Drinking Water Quality, Health Canada, 2010). In contrast to the deeper till/bedrock and bedrock chemistry, the overburden chemistry appears to be slightly higher in sodium, chloride, and TDS concentrations, and lower in alkalinity, organic carbon, and trace metals concentrations.
- In the till/bedrock, all parameters except iron (average 517 µg/L) and manganese (average 442 µg/L) meet GCDWQ. The till/bedrock chemistry typically has a higher total organic carbon concentration (mean 27.5 mg/L, maximum 120 mg/L) than the other units.
- In the bedrock, GCDWQ are typically exceeded for iron (average 1469 µg/L) and manganese (mean 286 µg/L). In comparison to the overburden wells, the bedrock typically has higher concentrations of alkalinity, pH, copper, iron, and zinc.

During field investigations carried out by AtkinsRéalis in September 2023, 18 new samples were collected to analyze the general groundwater chemistry of the pit area. The locations of water samples collected in 2012 and 2023 are presented in Figure B7 and a graphic Piper diagram of the 2012 water chemistry data is presented in **Figure 2-3**. The results of the 2023 field sampling program will be considered in a subsequent report, as field investigations were ongoing at the time of writing this report. Laboratory results for 2012 are available in Appendix G.

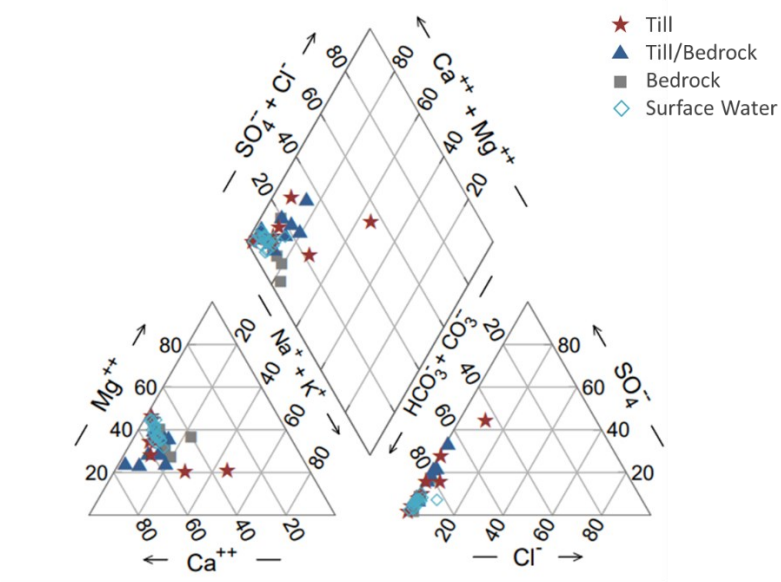

Figure 2-3: Piper Diagram for 2012 Samples

2.5.5 Hydraulic Conductivity

2.5.5.1 Overburden

In the study area, the hydraulic conductivity (K) of the overburden (till) was measured at 6 wells (Figure B8), including 2 in the pit footprint (ROB-11-05B and ROB-11-13B). The hydraulic conductivities estimated from in situ hydraulic tests (slug tests) are presented in **Table 2-5**. An average hydraulic conductivity of $1.2x10^{-6}$ m/s was obtained for the till, by calculating the geometric mean of the measurements. The deepest wells where the hydraulic conductivity was measured are BH-GE-03 and BH-GE-06, with the base of the screened interval at a depth of 15.5 m.

The hydraulic conductivity of till/bedrock was also estimated at 4 wells screened at the till/shallow bedrock contact. The geometric mean of the till/bedrock hydraulic conductivity ($1.8x10^{-7}$ m/s) is about an order of magnitude lower than the till, indicating a probable drop in hydraulic conductivity in the lower till or in the surface bedrock. A difference of one order of magnitude for minimum and maximum values was also observed between the till and the till/bedrock. The deepest well where hydraulic conductivity was measured is ROB-11-17, for which the base of the screened interval is at a depth of 47.7 m.

Hydraulic conductivity values for the overburden were also estimated from grain size distribution curves by empirical methods. The results were relatively similar to the slug tests and can be found in the Stantec report (2012a).

Table 2-5: Hydraulic Conductivities Estimated Through Slug Tests in the Overburden (Stantec, 2012)

ID	Screened HSU*	K (m/s)	Geometric Mean K (m/s)	Min. K (m/s)	Max. K (m/s)

2.5.5.2 Bedrock

In the study area, bedrock hydraulic conductivity (K) was measured in 24 wells (Figure B8), mostly located south of Long Lake. The hydraulic conductivities estimated from in situ hydraulic tests (slug tests) are presented in **Table 2-6**. An average hydraulic conductivity of $1.2x10^{-7}$ m/s was obtained for the bedrock, by calculating the geometric mean of the measurements. The deepest well where hydraulic conductivity was measured is BH-TF-01A, for which the base of the screened interval is at a depth of 23.6 m.

Table 2-6: Hydraulic Conductivities Estimated Through Slug Tests in the Bedrock (Stantec, 2012)

2.5.5.3 Faults

In the study area, deep bedrock hydraulic conductivity (K) was measured through a series of packer injection tests in 2 inclined boreholes: RBR-12-01 and RBR-12-02 (**Table 2-7**). The packer tests were performed by Stantec in 2012 within the proposed pit footprint (Figure B8).

Table 2-7: RBR-12-01 and RBR-12-02 Coordinates

ID	X NAD27 Zone 19 UTM	Y NAD27 Zone 19 UTM	Ground Elevation (masl)	Dip	Azimuth	Overburden Thickness (m)	Down Hole Depth (m)
RBR-12-01	632774	5855885	573	-60	270	39	225
RBR-12-02	632131	5855010	581	-60	270	14	300

The injection limit ($1x10^{-5}$ m/s) was reached during RBR-12-01 testing, at a vertical depth in the bedrock of approximately 100 m (about 160 m along the borehole) revealing an interval of pulverized sandy bedrock in the Sokoman formation (**Figure 2-4**). Core photos of the entire length of each borehole are presented in Appendix E. These photos show a bedrock with intense weathering intervals. Histogram summary plots, geological logs and basic geotechnical logs are also presented for each borehole in Appendix H.

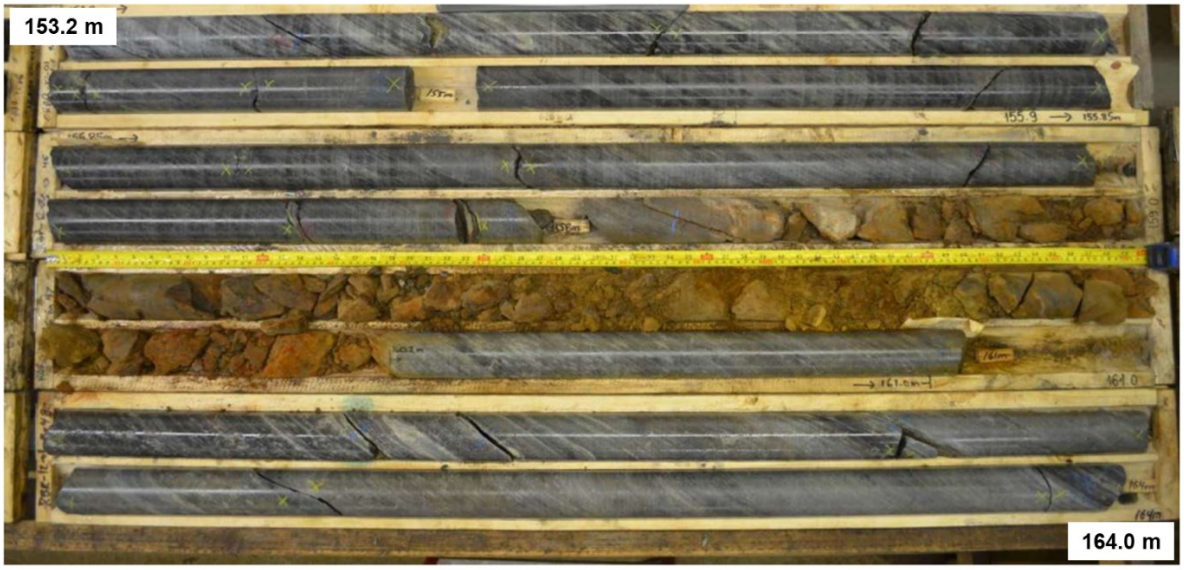

Figure 2-4: Intense Weathering Interval at RBR-12-01 (from Stantec, 2012)

As shown in Figure B8, RBR-12-01 and RBR-12-02 are both located in the center of the proposed pit. Average hydraulic conductivities of 2.4 $x10^{-6}$ and 1.5 $x10^{-6}$ m/s were obtained for the RBR-12-01 and RBR-12-02 respectively, by calculating the geometric mean of the measurements. Packer tests results tables for each borehole are presented in Appendix I and variations of hydraulic conductivity with depth (along borehole and vertical) are presented in **Figure 2-5**.

Local high hydraulic conductivities (in comparison to the geometric average) intervals from the packer tests are attributable to the presence of the Central fault, within the Sokoman formation. Consequently, an estimate of fault hydraulic conductivity can be made on the basis of the highest values estimated in packers, i.e., above $1x10^{-5}$ m/s. For all calculations and estimations (and production of **Figure 2-5**), a hydraulic conductivity of $5x10^{-5}$ m/s was assumed for these intervals.

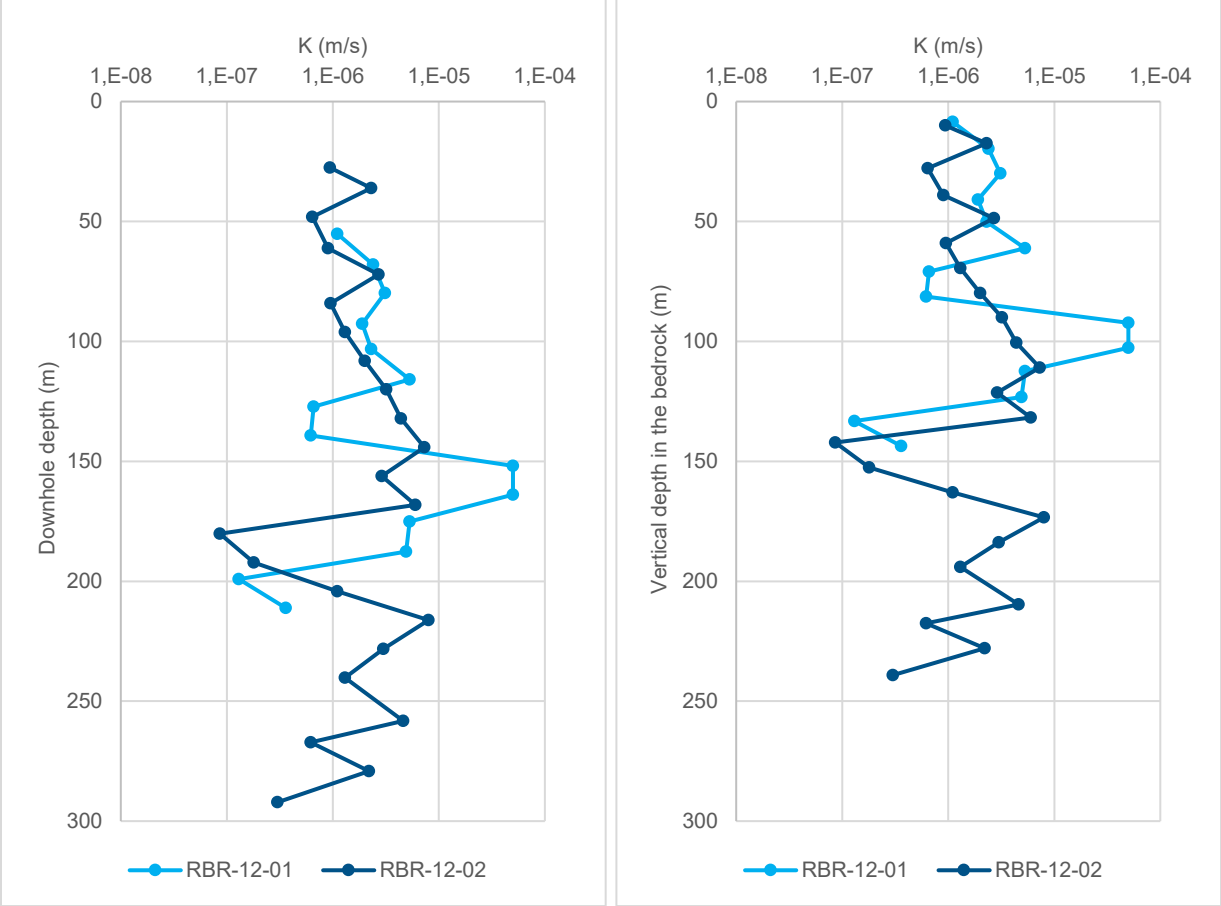

Figure 2-5: Borehole Packer Permeability Tests with Depth at RBR-12-01 and 02 (Stantec, 2012)

2.5.6 Hydrostratigraphy

Figures B9 and B10 present geological cross-sections through the Rose Pit that illustrate the interpreted overburden thickness, faults, bedrock geology and the proposed mine (pit shell) near RBR-12-01 and RBR-12-02, where the bedrock hydraulic conductivity variations with depth are the best known. Based on the data available, the hydrostratigraphy of the conceptual model was divided into 4 units: the till, the bedrock surrounding the total pit depth, the faults, and the deep bedrock beneath the maximum pit depth. The hydraulic conductivity of each unit is based on the geometric mean data of the measured values and is summarized in **Table 2-8**.

Table 2-8: Hydraulic Conductivity of Each Hydrostratigraphic Unit

Hydrostratigraphic Units	Approximate Depth Interval (m)	Geometric Mean of Hydraulic ConductivityK (m/s)
Overburden	0-60	1.2E-06
Bedrock	0-450[1]	1.2E-07
Deep Bedrock	450-650	1.0E-08
Faults	0-450	≥1.0E-05

Note:

1: The separation between bedrock and deep bedrock is based on the maximum pit depth of 450 m.

A cross-section showing the hydrostratigraphic units in the hydrogeological model (Feflow model) is presented in Figures B9 and B10 for each geological cross-section. For mesh simplification purposes, the Katsao-Wishart and the Central fault are represented as vertical zones of higher hydraulic conductivity with constant thicknesses of 50 and 30 m, respectively. Since the thickness and hydraulic conductivity of the lake-bottom sediments are unknown, it was assumed that the faults were hydraulically connected to the lakes, crossing the overburden layer.

Although the hydraulic conductivity of the bedrock is not known below 250 m vertical depth, the hydraulic conductivity of the bedrock unit was attributed to the entire bedrock surrounding the pit in a conservative approach (from the surface to the maximum pit depth, 450 m). A value of $1x10^{-8}$ m/s was assumed for the deep bedrock unit (below the pit), since bedrock generally decreases in permeability with depth (Stober and Bucher, 2007).

3. Groundwater Flow Model

A preliminary estimate of groundwater open pit mine inflows was made using a numerical model of the area. The following sections describe the steps involved in building and calibrating the model before dewatering.

3.1 Software Description

The modelling was conducted using the FEFLOW software, developed by WASY Institute in Germany (DHI, 2005). FEFLOW is a robust numerical groundwater model capable of considering all aspects including mining, processing, mine waste management, and the management (diversion, impoundment, treatment) of groundwater. In this study, the groundwater flow was simulated via Richard's equation representing unsaturated or variably saturated media.

3.2 Model Mesh

The hydrogeological FEFLOW model domain covers an area of approximately 200 km^2. This area was discretized using a mesh composed of 816,312 triangular prismatic elements of variable dimensions (Figure B11).

Horizontally, meshing and cell sizes have been adapted to adequately represent the local site infrastructure and anticipated hydraulic gradients. Average cell sizes are about 40 m inside the pit area and 5 m around the faults. Vertically, the model is composed of 29 layers of variable thicknesses. The mesh was also refined vertically for the overburden and along the pit depth. The overburden is discretized into 3 layers with an average thickness of 4.5 m. The bedrock surrounding the pit is discretized into 23 layers with an average thickness of less than 25 m. The deep bedrock under the pit is discretized into 5 layers with an average thickness of 25 m.

3.3 Boundary Conditions

The boundary conditions applied to the hydrogeological model are presented in Figure B11. The model domain is bound by physical boundaries that extend from the topographic highs west of Daviault Lake, where a no flow condition is applied, to Wahnahnish Lake in the east, where fixed head conditions are applied to represent the natural flow from Wahnahnish Lake to Labrador City.

To the north, the model boundary follows a hydrographic limit to a topographic low near Labrador City. To the south, the model boundary follows a succession of topographic highs (no flow boundary condition) which correspond to the catchment basin limits, then joins Wahnahnish Lake.

Major lake water elevations are assumed to represent groundwater levels. Based on topographic data and punctual lake water level measurements, a fixed head boundary condition was applied on Daviault, Molar, Pike, Mills, Long and Riordan lakes. Fixed head values used for each lake are presented in **Section 2.4**.

The natural surface drainage due to the hydrographic network was represented by drain boundary conditions (seepage face). These boundary conditions correspond to constant head boundaries with a value equal to the elevation of the surface and with a flow constraint which only allows water to exit the model. Drain boundary conditions were applied to topographic lows and valley floors where streams normally form.

Different recharge rates were used based on the topography of the area: from 35 to 150 mm/year on the topographic highs and no recharge on the topographic lows or steep slopes.

3.4 Model Calibration

During the model calibration process, the numerical model parameters, hydraulic conductivity and recharge, and boundary conditions are adjusted within reasonable ranges to obtain an acceptable match between measured and simulated heads (ASTM D5981-96, 2002).

The hydrogeological model was calibrated in steady state against water levels from 29 piezometers, measured between November 2011 and June 2012. The piezometers are located on the topographic highs at the periphery of the pit and in the topographic low in the center of the pit. The piezometers screens intercept the till, the till/bedrock, and the bedrock.

The normalized root mean squared error (NRMSE) method was chosen to quantitatively evaluate the goodness-of-fit between the measured and simulated heads. The following equation was used to calculate the NRMSE:

$$NRMSE\ (\%) = \frac{1}{(h_{max} - h_{min})} \times \left[\frac{1}{N}\sum_{i=1}^{N}(h_s - h_m)^2\right]^{\frac{1}{2}}$$

Where:

N: Number of observations

h_s: Simulated head (m)

h_m: Measured head (m)

h_{max}: Maximum measured head (m)

h_{min}: Minimum measured head (m)

Mainly, during the calibration process, the hydraulic conductivity of the bedrock unit was reduced by half an order of magnitude to raise simulated hydraulic heads in topographic high areas (**Table 3-1**). The hydraulic conductivity from other units remained relatively intact. The recharge was also increased to 130 mm/year on the topographic highs in the Rose Pit area (Figure B11). Calibrated hydraulic conductivities for each of the units in the model are presented in Figure B12.

Table 3-1: Estimated and Calibrated Hydraulic Conductivity

Hydrostratigraphic Units	Hydraulic Conductivity K (m/s)	
	Mean selected value estimated through slug tests and packer tests	Calibrated values
Overburden	1.2E-06	1.0E-06
Bedrock	1.0E-07	5.0E-08
Deep Bedrock	1.0E-08	1.0E-08
Faults	≥1.0E-05	1.0E-05

In general, the model calibration is satisfactory, as shown by the alignment of points on the calibration line (**Figure 3-1**). The measured and simulated heads, as well as their residuals are presented in Appendix J. An NRMSE of 9.5% was obtained for the calibrated model, which is below the generally accepted target of 10% (Robertson GeoConsultants Inc. and SRK Consulting, 2012).

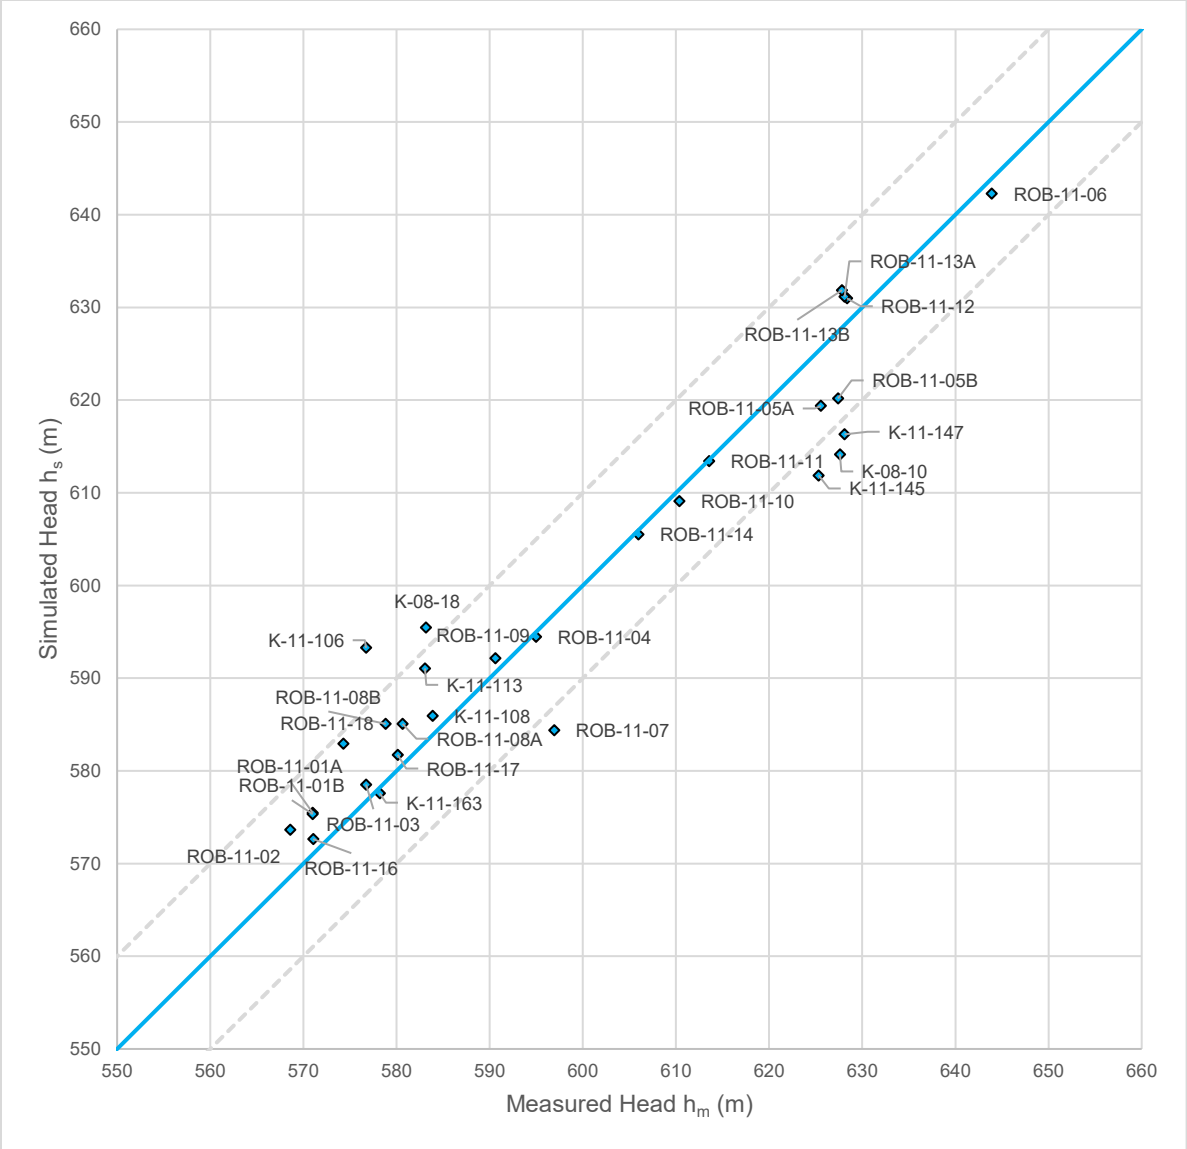

Figure 3-1: Hydrogeological Model Calibration Line

As shown in **Figure 3-1**, simulated hydraulic heads are underestimated by approximately 10 m at K-08-10, K-11-145, and K-11-147. Those wells are all located on the topographic high, in the eastern part of the pit. Simulated heads are also underestimated at ROB-11-07, which is located on a steep slope in the southwestern part of the pit.

Simulated heads are overestimated by 10 m at K-08-18, located hydraulically downstream of the previous wells. To the west of the pit, on the hillside, simulated heads are also overestimated by 10 m at K-11-106 whereas heads at ROB-11-06, upstream, are perfectly calibrated.

The over- or underestimation of simulated hydraulic heads at certain wells demonstrates the difficulty of representing abrupt groundwater level variations associated with slopes and complex geology.

Another challenge for the model calibration is the fact that water levels data come from measurements taken at different times of the year, between November 2011 and April 2012. This means that a synchronous data set to calibrate all the wells is not available, which can lead to greater error in the calibration. It is worth noting that the mean average error (MAE) of the calibrated model is 4.5 m (Appendix J), which is less than the local groundwater fluctuation of 6.37 m, which was measured at ROB-11-06 between March and June 2012. The calibration will be refined subsequently, based on new data from level logger installed during 2023 field work.

The calibrated model represents what will subsequently be referred to as the base case scenario.

3.5 Simulated Piezometry

As shown in Figure B13, the simulated piezometry for the base case scenario satisfactorily reproduces the measured piezometry values. The simulated groundwater flow follows the topography and converges towards the valley center, where the flow direction is towards Pike Lake.

The simulated piezometry is also presented along a NW-SE cross-section across the pit (Figure B14). The section shows the flow direction from the topographic highs to the local lows, like Rose Lake and Elfie Lake, where the water level is at the surface or artesian.

3.6 Sensitivity Analysis

A sensitivity analysis of a hydrogeological model is usually conducted to define which of the model parameters has the most influence on the modelling results. It can also be used to adapt the calibration strategy or to validate the impact of insufficient data on the modelling results. The parameters selected for this sensitivity analysis are:

- The hydraulic conductivity of each unit, which was increased and decreased by an order of magnitude;
- The recharge rate, which was increased by 50%;
- The water elevation of Pike Lake, considering that the lake is dried up; and
- The faults connection to Pike Lake through the overburden (**Figure 3-2**).

Following the variation of these parameters, different types of error (NRMSE, MAE, RMS, and Standard Deviation) were compared to the base case scenario as shown in **Table 3-2**. Based on this sensitivity analysis, the overburden and above all, the bedrock unit hydraulic conductivity, were determined to have a major impact on the calibration, as can be seen with the higher NRMSE values (SA3 and SA4). It should be noted that a less permeable deep bedrock value ($1x10^{-9}$ m/s) provides slightly better calibration statistics (SA6). However, to evaluate a conservative case, a more permeable deep bedrock value of $1x10^{-8}$ m/s was selected for future dewatering flow rate estimations.

Other parameters like the recharge rate (SA9), Pike Lake water level (SA10), and the faults connection through the overburden (SA11), seem to have a lesser impact on the calibration.

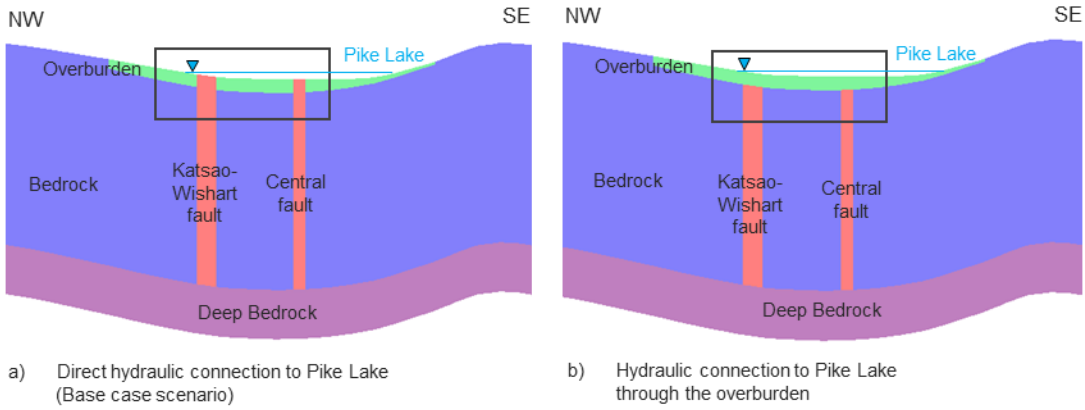

Figure 3-2: Conceptual Representation of the Faults Connection to Pike Lake through the Overburden in the Hydrogeological Model

Table 3-2: Groundwater Flow Sensitivity Analysis (SA) Results

Sensitivity Analysis (SA) Scenario	HSU Hydraulic Conductivity (m/s)				Recharge Rate (mm/yr)	Pike Lake Water Elevation (m)	Faults Through Overburden	Normalized Root Mean Square Error NRMSE	Mean Absolute Error MAE (m)	Root Mean Square RMS (m)	Standart Deviation σ (m)

Change from the Base Case

4. Rose Pit Dewatering

4.1 Dewatering Results at the End of Operations (Y26)

4.1.1 Analytical Results

In 2012, Stantec estimated pit dewatering rates Q (m^3/day) at the end of Operations using an analytical solution, the "Darcy Approach":

$$Q = K \cdot i \cdot A$$

where inflow is proportional to hydraulic conductivity K (m/s), hydraulic gradient i (m/m) and a cross-sectional area of porous medium, A (m^2).

These estimates assume a pit perimeter of 8,627 m, an average seepage face height of 10 m during operations and a conservative hydraulic gradient of 0.5 towards the pit wall. These values reflect potential inflows under final pit development as the perimeter chosen for this exercise represents the maximum pit footprint at ground surface and thus provides an upper bound value of estimated pit inflow (Stantec, 2012a).

- The estimated potential inflow to the pit through the silty sand glacial till overburden material ranges from 1,886 m^3/day to 7,156 m^3/day with an average of 4,472 m^3/day (Stantec, 2012a).
- Using similar pit morphology assumptions and the K values from two packer tests in bedrock (RBR-12-01 and RBR-12-02), the estimated inflow to the pit through bedrock could theoretically range from 321 m^3/day to 29,815 m^3/day with an average of 6,187 m^3/day (Stantec, 2012a).

The above results are summarized in **Table 4-1**.

Table 4-1: Pit Dewatering Rate Based on Darcy Approach (Stantec, 2012a)

Analytical Dewatering Scenario	Hydraulic Conductivity (m/s)[1]			Pit Outflow Rate (m^3/day)[2]		
	Min.	Max.	Average	Min.	Max.	Average
Till	5.1E-07	1.9E-06	1.2E-06	1,886	7,156	4,472
Bedrock	8.6E-08	8.0E-06[3]	1.7E-06[4]	321	29,815	6,187
Till + Bedrock	na	na	na	2,207	36,971	10,659

Notes:

1: K data for till and bedrock are from ROB-11-05B, 13B and 20 completed in the upper silty sand, and the bedrock is represented by two inclined boreholes RBR-12-01 and RBR-12-02 in bedrock, and ROB-11-01 and ROB-11-02 completed across the deep till/bedrock interface (Stantec, 2012a).

2: Minimum, maximum, and average pit outflow rates are based on minimum, maximum and geometric average of the hydraulic conductivity for the till and the bedrock, estimated by Stantec (2012a).

3: This value was measured at RBR-12-02 at a vertical depth of around 190 m. However, this maximum does not consider the two RBR-12-01 intervals where the injection limit of $1x10^{-5}$ m/s was reached (Appendix I).

4: The average bedrock hydraulic conductivity is only based on the packer tests results realized at RBR-12-01 and 02. However, based on current understanding of the site, some hydraulic conductivity intervals of these boreholes are more representative of fault zones, but the distinction between bedrock and fault zones is not considered with the analytical approach.

Stantec's estimates, derived from Darcy's analytical approach, represent a first-order preliminary estimate of potential pit inflows for overburden and bedrock. Analytical models are typically used to represent simple systems or to illustrate broad, generalized effects of different parameter assumptions whereas numerical models are typically used to represent more complex systems (Robertson GeoConsultants Inc. and SRK Consulting, 2012). Groundwater numerical models are powerful tools to conceptualize and quantify current conditions (synthesize existing information), and in this case, understand system dynamics to identify and quantify controlling and significant processes (Robertson GeoConsultants Inc. and SRK Consulting, 2012). Among other things, the existence of the following gives the hydrogeological system its complex character and justifies the need of a numerical model for the rest of the project:

- A highly folded and metamorphosed bedrock geology, with sub-vertical formations;
- A variable thickness of overburden that could present preferential flowpaths (piping);
- Identification of 2 sub-vertical faults, potentially intercepting nearby lakes;
- The presence of nearby lakes, which could lead to significant dewatering flow rates on the one hand, and the potential drying up of the lakes on the other;
- Potential drawdowns or groundwater quality impacts on receptors (such as Duley Lake Provincial Park to the north of the site);
- Impacts of the interactions between all the components of this complex system;
- Future 3D data acquisition.

Given the limited amount of data available in 2012, the Darcy approach used by Stantec was reasonable at that time. However, the Darcy approach is unable to consider the complexity of the site. In addition, the availability of a 3D geological Leapfrog model offers a unique opportunity to support the construction of a 3D groundwater numerical model.

The dewatering results of the 3D numerical Feflow model are presented in the following section.

4.1.2 Numerical Results

To estimate dewatering rates, a steady-state simulation was carried out using the pit's maximum depth (450 m) at the end of operations (Year 26). In a conservative approach, a baseline scenario was selected for infrastructure design purposes (selected case), assuming the faults hydraulic conductivity was 5 times higher than the base case (i.e., $5x10^{-5}$ m/s). The hydraulic conductivity of the faults in the base case ($1x10^{-5}$ m/s) corresponds to the injection limit reached during packer tests in RBR-12-01.

The other assumptions and parameters, like constant lake levels during dewatering operations, the fault connection through the overburden or other units' hydraulic conductivity, remain identical to the base case.

Based on the above assumptions, the simulated pit dewatering flow rate for the selected case would be 40,849 m^3/day, while that of the base case would be 12,432 m^3/day (**Table 4-2**). It was observed that of the estimated 40,849 m^3/day, 29,460 m^3/day would originate directly from Pike Lake, which is located north of the pit. The dewatering rate for the selected case is higher than for the base case, due to the increased hydraulic conductivity of the faults. Because of its proximity to the pit and hydraulic connection to the fault, Pike Lake's contribution would be greater than that of the other lakes. The second largest inflow rate would be from Daviault Lake (7,017 m^3/day), which in the model, is hydraulically connected to the pit by the Katsao-Wishart fault.

Water contributions during dewatering (inflow rate) from lakes Daviault, Mills and Molar for the base and the selected case are presented in **Table 4-2**.

Table 4-2: Pit Dewatering Rate and Lakes Contribution (Y26)

Numerical Dewatering Scenario (Y26)	Pit Outflow Rate (m^3/day)	Inflow Rate (m^3/day)			
		Pike Lake	Mills Lake	Daviault Lake	Molar Lake
Base Case[1]	12,432	7,051	520	1,133	84
Selected Case[2]	40,849	29,460	525	7,017	110

Notes:

1: The base case represents the calibrated scenario, with faults connection through the overburden and K_{faults} = $1x10^{-5}$ m/s.

2: The selected case represents a conservative scenario (higher dewatering flow rate) selected for the water infrastructure design, with faults connection through the overburden and K_{faults} = $5x10^{-5}$ m/s.

A simulated piezometric map, representing the final phase of pit dewatering (final depth of the mine pit) and assuming steady state conditions, is presented in Figure B15. The influence of dewatering would extend preferentially in a NE-SW alignment, along the more permeable fault zones. Simulated hydraulic heads are also presented at Y26 in a NW-SE cross-section in Figure B16 showing that the drawdown could be significant, especially in topographic highs areas.

The estimation of pit dewatering flow rates relies on a set of conservative conceptual assumptions, such as:

- The representation of faults as homogeneous zones of high hydraulic conductivity ($5x10^{-5}$ m/s) directly connected to the lakes (Pike and Daviault);
- The representation of faults throughout the pit's depth (450 m);
- The extension of the Katsao-Wishart fault to Daviault lake, with a high hydraulic conductivity ($5x10^{-5}$ m/s). It is worth noting that, based on the regional geology, the Katsao-Wishart fault is interpreted to be continuous up to Daviault lake. However, the geological continuity of the fault does not necessarily translate to a high hydraulic conductivity zone that would extend over the 2.6 kilometres separating the lake from the pit. This hypothesis is therefore conservative with respect to dewatering rates;
- Maintaining constant water levels for Daviault and Pike lakes throughout dewatering, which maintains a high hydraulic gradient towards the pit.

4.2 Sensitivity Analysis

4.2.1 Dewatering at the End of Y26

Several dewatering sensitivity analyses (DSA) were carried out by varying the hydraulic conductivity of the hydrostratigraphic units, the recharge rate, as well as the faults' connection through the overburden and to the lakes (Daviault and Pike). For each scenario, the impact on the pit dewatering flow rate is shown in **Table 4-3**.

For comparison, Stantec results from an analytical solution (Darcy approach) have also been included in **Table 4-3**. The average (10,659 m^3/day) and the maximum (36,971 m^3/day) dewatering rates from the analytical solution are relatively similar to the base case (12,432 m^3/day) and the selected case (40,849 m^3/day) results from the numerical model, respectively. Two main facts explain these similarities: on one hand, the numerical model is based on the same 2012 data used in the analytical solution, since no new data was available at the time of this study; and on the other hand, the 3D numerical model has not been unnecessarily made more complex at this stage, with 4 hydrostratigraphic units represented in the model. New data acquisition would support the updating of a more complex model that would serve as the basis for a more detailed design.

The results of the sensitivity analysis (DSA1 to DSA13) confirm what had previously been established between the base case and the selected case: the hydraulic conductivity of the faults seems to be a major factor controlling pit dewatering rate. Indeed, in the DSA7 and DS8 scenarios, the faults' hydraulic conductivity varies by an order of magnitude around the base value. For the higher value of $1x10^{-4}$ m/s, the dewatering rate is increased by more than 6 times compared to the base case. On the contrary, the greatest reduction in dewatering rates is observed for DSA8, where the hydraulic conductivity of the faults is reduced to $1x10^{-6}$ m/s.

The bedrock surrounding the pit also seems to play a significant role (DSA3), with dewatering rates increased by a factor of 3 when the hydraulic conductivity of the bedrock is an order of magnitude higher ($5x10^{-7}$ m/s).

Sensitivity analyses DSA14 to 16 illustrate the influence of the system's interconnectivity and the impact of conceptual modelling choices on dewatering results. In the case where a high hydraulic conductivity value is considered for the faults ($1x10^{-4}$ m/s), the results of DSA7 show that the dewatering flow rate could reach 76,121 m^3/day. However, in the case where the overburden, with a lower hydraulic conductivity ($1x10^{-6}$ m/s), overlies the faults, thereby limiting the water inflow from Pike Lake (DSA14), the flow would be reduced by a factor of 3 (i.e., 25,553 m^3/day). This scenario limits the influence of the connection between faults and lakes by considering a buffer zone where flow is limited. Based on the overburden data in the pit area, it is likely that a certain thickness of till or lake-bottom sediment is overlying the fault zones or fractured bedrock beneath Pike Lake. However, the overburden properties (thickness and hydraulic conductivity) under the lake have not been studied.

Scenario DSA15 shows the influence of the hydraulic connection between the Katsao-Wishart fault and Daviault Lake on dewatering flow rates. When this fault is not hydraulically connected to the lake, the flow seems to decrease to 59,402 m^3/day.

Scenario DSA16 considers that the faults are not connected to Pike Lake through the overburden and that the Katsao-Wishart fault is not connected to the overburden. In contrast to DSA7, the pit dewatering flow rate would be considerably reduced. This simulation shows how the accumulation of different conceptual assumptions can lead to significant variations in pit dewatering flow. In this case, they reduce the initial flow rate by a factor of 4.

The sensitivity analysis highlights the flow dynamics during the final phase of pit dewatering, and the interactions between the various modelling parameters. This exercise also helps define the priority issues to be addressed during future fieldwork.

Table 4-3: Dewatering Flow Rate Sensitivity Analysis (DSA) Results

Dewatering Sensitivity Analysis (DSA) Scenario	Hydraulic Conductivity K (m/s)				0<R<130 (mm/yr)	Pike Water Elevation (m)	Faults Through Overburden	K-W Fault Connected to Daviault	Y26 Pit Flow Rate (m3/day)

Notes:

1: Analytical results are based on the Darcy approach (Stantec, 2012a).

2: The base case represents the calibrated scenario.

3: The selected case represents a conservative scenario (higher dewatering flow rate) for the water infrastructure design.

Change from the Base Case

4.2.2 Yearly Dewatering, Y01 to Y26

Using the 3D numerical model, dewatering flow rates for each year of operation, from year 1 to year 26, for the base case and the selected case, were estimated (**Figure 4-1**). For each year, a steady-state simulation is run using the pit shell of the corresponding year. As a reminder, the dewatering rate results for the selected case are higher than those for the base case due to the hydraulic conductivity of the faults, which is 5 times higher for the selected case (from $1x10^{-5}$ to $5x10^{-5}$ m/s). The impact of fault hydraulic conductivity on dewatering flow is visible from the beginning of Operations since faults are represented as outcrops in the model.

Dewatering rates for one-quarter, one-half and three-quarters of the total pit depth were estimated based on the total pit depth. The surface elevation used to calculate pit depth is 570 masl, the approximate elevation of the centre of the valley. For each year, the dewatering results are presented in **Figure 4-1**, for the base case and the selected case, considering the following:

- Elevation 443 masl represents approximately ¼ of the pit's total depth, which is projected to be reached by Y05.
- Elevation 315 masl represents approximately ½ of the pit's total depth, which is projected to be reached by Y14.
- Elevation 188 masl represents approximately ¾ of the pit's total depth, which is projected to be reached by Y24.
- Elevation 60 masl represents approximately the final pit's depth, which is projected to be reached by Y26.

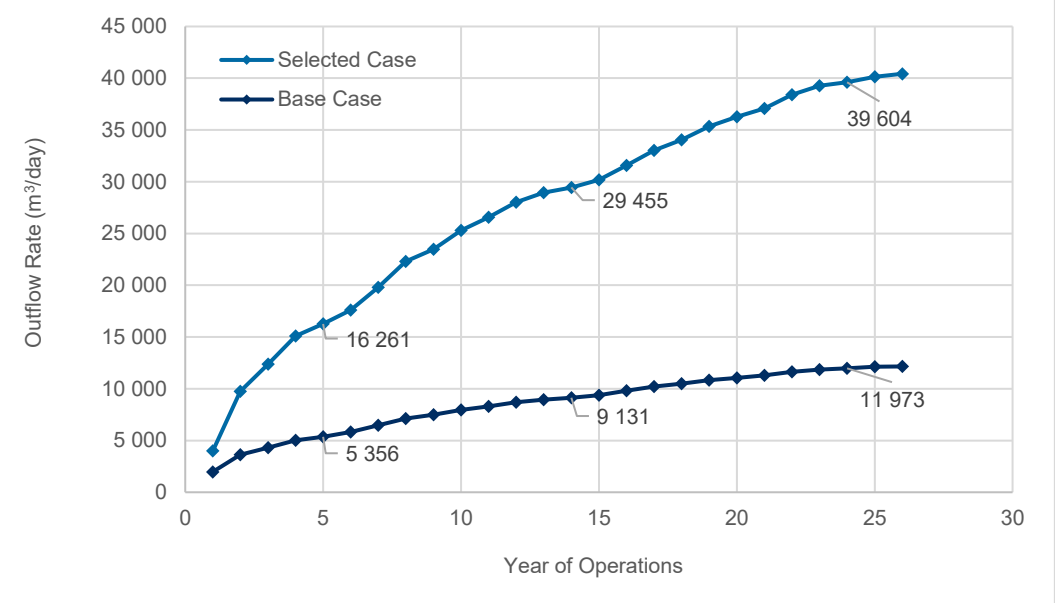

Figure 4-1: Dewatering Rates During Operations Y01 to Y26

An estimate of the pit outflow rate and lakes inflow rate was also evaluated in the first years of operation (Y05) for the base case and the selected case. **Table 4-4** shows the results of this analysis.

Table 4-4: Pit Dewatering Rate and Lakes Contribution (Y05)

Dewatering Scenario (Y05)	Pit Outflow Rate (m^3/day)	Inflow Rate (m^3/day)			
		Pike Lake	Mills Lake	Daviault Lake	Molar Lake
Base Case[1]	5,356	2,458	183	184	11
Selected Case[2]	16,261	10,924	187	2,418	13

Notes:

1: The base case represents the calibrated scenario.
2: The selected case represents a conservative scenario (higher dewatering flow rate) selected for the water infrastructure design.

5. Limitations

Groundwater models present a simplified version of the geological and hydrogeological systems represented, as such, the hydrogeological model is subject to the following limitations:

- The model is a simplification of the significant variability of the hydraulic conductivities and hydrostratigraphic units that are usually encountered in fluvial and glacial deposits.
- Groundwater flow into the pit: The assumed water infiltration rate of 40,000 m^3/day needs to be narrowed with supplemental hydrogeological field data. A campaign is ongoing (Q4 2023, with drilling and packer tests) and a pumping test is also planned later. These campaigns aim to acquire the following missing information:
  - Measurement of bedrock hydraulic conductivity at depth using packer tests.
  - Characterization of fractured bedrock and fault zones using acoustic and optical televiewers.
  - Groundwater head characterization using Vibrating Wire Piezometers (VWP).
- The calibration of the 3D hydrogeological model is based on water levels measured in boreholes at various dates, and some lake water elevations are based on Lidar data:
  - No synchronous piezometry measurements in all selected boreholes in the pit area.
  - No synchronous piezometry measurements in the pit area and outside (tailings and waste rock area).
  - Limited continuous water level (pressure transducer) data available (less than a year).
  - Limited number of multi-level piezometers to characterize vertical hydraulic gradients.
  - No seasonal measurement of lake level variations.
- Hydraulic conductivity of the bedrock: The current 3D hydrogeological model of the pit is based on the hydraulic conductivity of the bedrock as defined by only two (2) packer tests, with limited vertical depth (approximately 250 m). A drilling campaign is underway to fill these data gaps.
- Faults and fractured zones:
  - Katsao-Wishart fault: This fault was identified by Stantec (2012), who defined the Wishart as a unit of very poor-quality bedrock. However, the extent of this poor-quality unit is not defined outside of the pit area. In particular, the connection between the poor-quality bedrock and the surrounding lakes (especially Pike and Daviault) is unknown. Furthermore, no hydraulic conductivity measurements are available for this fault zone. A drilling campaign is underway to cover these data gaps.
  - Central fault/fractured zones: Based on the interpretation of the televiewer surveys conducted between 2008 and 2012, as well as on the analysis of certain drill core sections, a highly fractured zone has been defined in the center of the pit. However, the spatial continuity and potential connection to the lakes of this fractured zone (or fault) are unknown because it is based on a limited number of boreholes. Furthermore, no hydraulic conductivity measurements are available for this fault zone.
- Pike Lake sediment characteristics and underlying overburden: The thickness and hydraulic conductivity of sediments under the various surrounding lakes, and especially under Pike Lake, remain unknown. Characterization of these sediments is important for estimating the degree of hydraulic connection between the lakes and the proposed pit. For the moment, the hydrogeological model considers a direct connection between the fault zones and the lakes (zero sediment thickness). Sediment characterization in Elfie Lake, End Lake, and Mid Lake is also necessary to understand if the infiltration rate of water from these lakes to Rose Pit could be a potential issue.

A drilling campaign is underway for additional data collection and the hydrogeological model will be updated subsequently. The completion of the following steps will help reduce the uncertainty in predicting groundwater dewatering flow rates:

- Evaluate fault connectivity to Pike Lake by characterizing overburden and lakebed sediments with field investigations;
- Conduct a pumping test to evaluate the connectivity and extent of the fracture network;
- Install pressure transducers in the northern sector of the pit to assess potential groundwater drawdown in the direction of Pike Lake during the pumping test;
- Install pressure transducers in the central and southwestern sector of the pit to assess potential groundwater drawdown in the direction of Daviault lake during the pumping test.

APPENDICES

Appendix A. Scope of Report

SCOPE OF REPORT

1. Use of report

a. Use of report

This report has been prepared, and the work mentioned herein was carried out by AtkinsRéalis Canada Inc. (AtkinsRéalis) exclusively for the client (the Client), to whom the report is addressed, and who took part in developing the scope of work and understands the limitations. The methodology, findings, recommendations and results cited in this report are based solely on the scope of work and are subject to the requirements of time and budget, as described in the offer of services and/or the contract under which this report was issued. Use of this report or any decision based on its content by third parties is the sole responsibility of the third parties. AtkinsRéalis is not responsible for any damage incurred by third parties due to the use of this report or of any decision based on its content. The findings, recommendations and results cited in this report (i) have been prepared in accordance with the skill level normally demonstrated by professionals operating in similar conditions in the sector, and (ii) are determined according to the best judgment of AtkinsRéalis, taking into account the information available at the time the report was prepared. The professional services provided to the Client and the findings, recommendations and results cited in this report are not subject to any guarantee, express or implied. The findings and results cited in this report are only valid on the date of the report and may be based in part on information provided by third parties. This report may require modifications in case of inaccurate information, discovery of new information or changes in project parameters. The results of this study are in no way a guarantee that the site in the study is free of contamination. This report must be considered as a whole and its parts or sections must not be taken out of context. If discrepancies were to appear between the draft and the final version of this report, the final version shall prevail. Nothing in this report is mentioned with the intention to provide or constitute legal advice. The content of this report is confidential and proprietary. It is prohibited for any person other than the Client to reproduce or distribute this report, to use or take a decision based on its content, in whole or in part, without the express written permission of the Client and AtkinsRéalis.

b. Modifications to project

The evidence, interpretations and recommendations contained in this report relate to the specific project as described in the report and do not apply to any other project or any other site. If the project is modified from a perspective of design, dimensioning, location or level, AtkinsRéalis must be consulted to confirm that the recommendations already given remain valid and enforceable.

c. Number of soundings

The recommendations in this report are intended only as a guide for the design engineer. The number of soundings to determine all subsurface conditions that may affect construction (costs, techniques, equipment, schedule) should normally be greater than that for the purpose of design. The number of sample sites and chemical analyzes as well as the sampling frequency and choice of parameters can influence the nature and extent of corrective actions as well as treatment or disposal technology and cost. Contractors bidding or subcontracting the work should rely on their own research and their own interpretations of the surveys' factual results to assess how underground conditions can affect their work and the cost of work.

d. Interpretation of data, comments and recommendations

Unless otherwise noted, data and results interpretation, comments and recommendations contained in this report are based, to the best of our knowledge, on environmental policies, criteria and regulations in force at the location of the project and on the production date of the report. If these policies, criteria and regulations are subject to change after submission of the report, AtkinsRéalis must be consulted to review the recommendations in the light of these changes. When no policy, criteria or regulation is available to allow for the interpretation of data and analytical results, comments or recommendations expressed by AtkinsRéalis are based on the best knowledge of the rules accepted in professional practice. The analyzes, comments and recommendations contained in this report are based on data and observations collected on the site, which come from sample work on the site. It is understood that only the data collected directly at the survey sites, sample sites and on the sample date are accurate and that any interpolation or extrapolation of these results to all or part of the site carries the risk of errors, which may themselves influence the nature and extent of the actions required on the site.

2. Sounding reports and interpretation of subsurface conditions

a. Soil and rock descriptions

The soil and rock descriptions given in this report are from classification and identification methods commonly accepted and used in the practice of geotechnical engineering. The classification and identification of soil and rock involves judgment. AtkinsRéalis does not guarantee that the descriptions will be identical in all respects to those made by another geotechnician possessing the same knowledge of geotechnical rules, but ensures accuracy only to what is commonly used in geotechnical practice.

b. Condition of soil and rock at sounding sites

The sounding reports only provide subsurface conditions and only at sounding sites. The boundaries between different layers on sounding reports are often approximate, rather corresponding to the transition zones and therefore subject to interpretation. The precision of subsurface conditions depends on the sounding method, frequency and method of sampling and consistency of the terrain encountered. The spacing between surveys, the sampling frequency and the type of sounding also reflect budgetary considerations and timelines that are outside the control of AtkinsRéalis.

c. Condition of soil and rock between sounding sites

The soil and rock formations are variable over a considerably large area. Subsurface conditions between sounding sites are interpolated and may vary significantly from the conditions encountered at sounding sites. AtkinsRéalis can guarantee the results at the site where sounding are conducted. Any interpretation of the conditions presented between sounding sites carries risks. These interpretations can lead to the discovery of conditions that are different from those that were expected. AtkinsRéalis cannot be held responsible for the discovery of different soil and rock conditions from those described elsewhere than at the site where soundings are conducted.

d. Groundwater levels

The groundwater levels provided in this report only correspond to those observed at the site and on the date indicated in the report and depends on the type of piezometric installation used. These conditions may vary based on the season or due to construction work on the site or on adjacent sites. These variations are beyond the control of AtkinsRéalis.

3. Contamination levels

The contamination levels described in this report (if within the scope) correspond to those detected at the site and on the date indicated in the report. These levels can vary based on the season or due to activities on the study site or on adjacent sites. These variations are beyond our control. Contamination levels are determined from the results of chemical analyzes of a limited number of soil, surface water or groundwater samples. The nature and degree of contamination between sample site may vary greatly. The chemical composition of groundwater at each sample site is likely to change due to groundwater flow, surface recharge conditions, stress of the formation investigated (i.e. pump or injection wells near the site) and natural seasonal variability. The accuracy of groundwater contamination levels depends on the frequency and the number of analyzes. The list of parameters analyzed is based on our best knowledge of the history of the site and the contaminants likely to be found on the site and is also a reflection of budgetary considerations and timelines. The fact that a parameter has not been analyzed does not exclude its presence at a concentration above the background noise or the detection limit of this parameter.

4. Study and work monitoring

a. Final phase verification

All design and construction details are not known at the time of issue of the report. It is therefore recommended that AtkinsRéalis's services be retained to provide light on the possible consequences of construction on the final work.

b. Inspection during execution

It is recommended that AtkinsRéalis's services be retained during construction to verify and confirm that groundwater conditions throughout the site do not differ from those given in the report and that the construction work will not have an adverse effect on the conditions of the site.

5. Changing conditions

The soil conditions described in this report are those observed during the study. Unless otherwise stated, these conditions are the basis for recommendations in the report. Soil conditions can be significantly affected by construction work (traffic, excavation, etc.) on the site or on adjacent sites. Excavation may expose the soil to changes due to humidity, drying or freezing. Unless otherwise indicated, the soil must be protected from these changes or rearrangements during construction. When conditions encountered at the site differ significantly from those provided in this report, due to the heterogeneous nature of the subsurface or due to construction work, it is the responsibility of the Client and the user of this report to notify AtkinsRéalis of changes and give AtkinsRéalis the opportunity to review the report's recommendations. Recognizing a change in ground conditions requires experience. It is therefore recommended that an experienced geotechnical engineer be dispatched to the site to see if conditions have changed significantly.

6. Drainage

Groundwater drainage is often required for both temporary and permanent project facilities. An incorrect drainage design or execution can have serious consequences. AtkinsRéalis cannot under any circumstance take responsibility for the effects of drainage unless AtkinsRéalis is specifically involved in the detailed design and monitoring of the drainage system's construction.

7. Environmental characterization – Phase I

This report was written after diligent research and evaluation of point data sources or information obtained from third parties that may present uncertainties, gaps or omissions. These sources of information are subject to change over time, for example, according to the progress of activities on the site and surrounding area. Phase I includes no testing, sampling or characterization analysis by a laboratory. Subject to exceptions, Phase I is based on the observation of visible and accessible components on the property and those nearby and could bring environmental harm to the quality of the land in the study. The property titles mentioned in this report are used to identify the former owners of the study site and cannot under any circumstance be considered as an official document for reproduction or other uses. Finally, any sketch, plan view or diagram appearing in the report or any statement specifying dimensions, capacities, quantities or distances are approximate and are included to help the reader visualize the property.

NOTES

In the pit and tailings area, interpolation is based on data from exploration and geotechnical drilling. Outside this area, on the periphery of the study zone, control points were added to compensate for the lack of information. Till thickness was estimated based on topography (between 1 and 5 m on the topographic highs and 20 m in the valleys)

NOTES

Fault locations are approximative and fault continuity is uncertain outside Rose pit area.

A major thrust fault, parallel to the strike of the deposit, has been interpreted at the Wishart and Katsao Formation contact in the northwest portion of the North Rose deposit (Katsao-Wishart fault).

A second fault (or fractured zone) have been interpreted in the Sokoman Formation, in the center of the pit (Central fault).

Three interpreted sub-vertical dip-slip faults bisect the deposits, trending roughly northwest-southeast. However, it is understood that more structures may be present based on review of aerial imagery. As a result of directional bias of the exploration boreholes, these structures are rarely intersected and are at present interpreted only through 3D geological interpolation.

Stantec's Pit Slope Design report (2012a) mentions the presence of a potential fault in the Menihek unit (syncline axis), however the existence or location of this fault was not confirmed during this study.

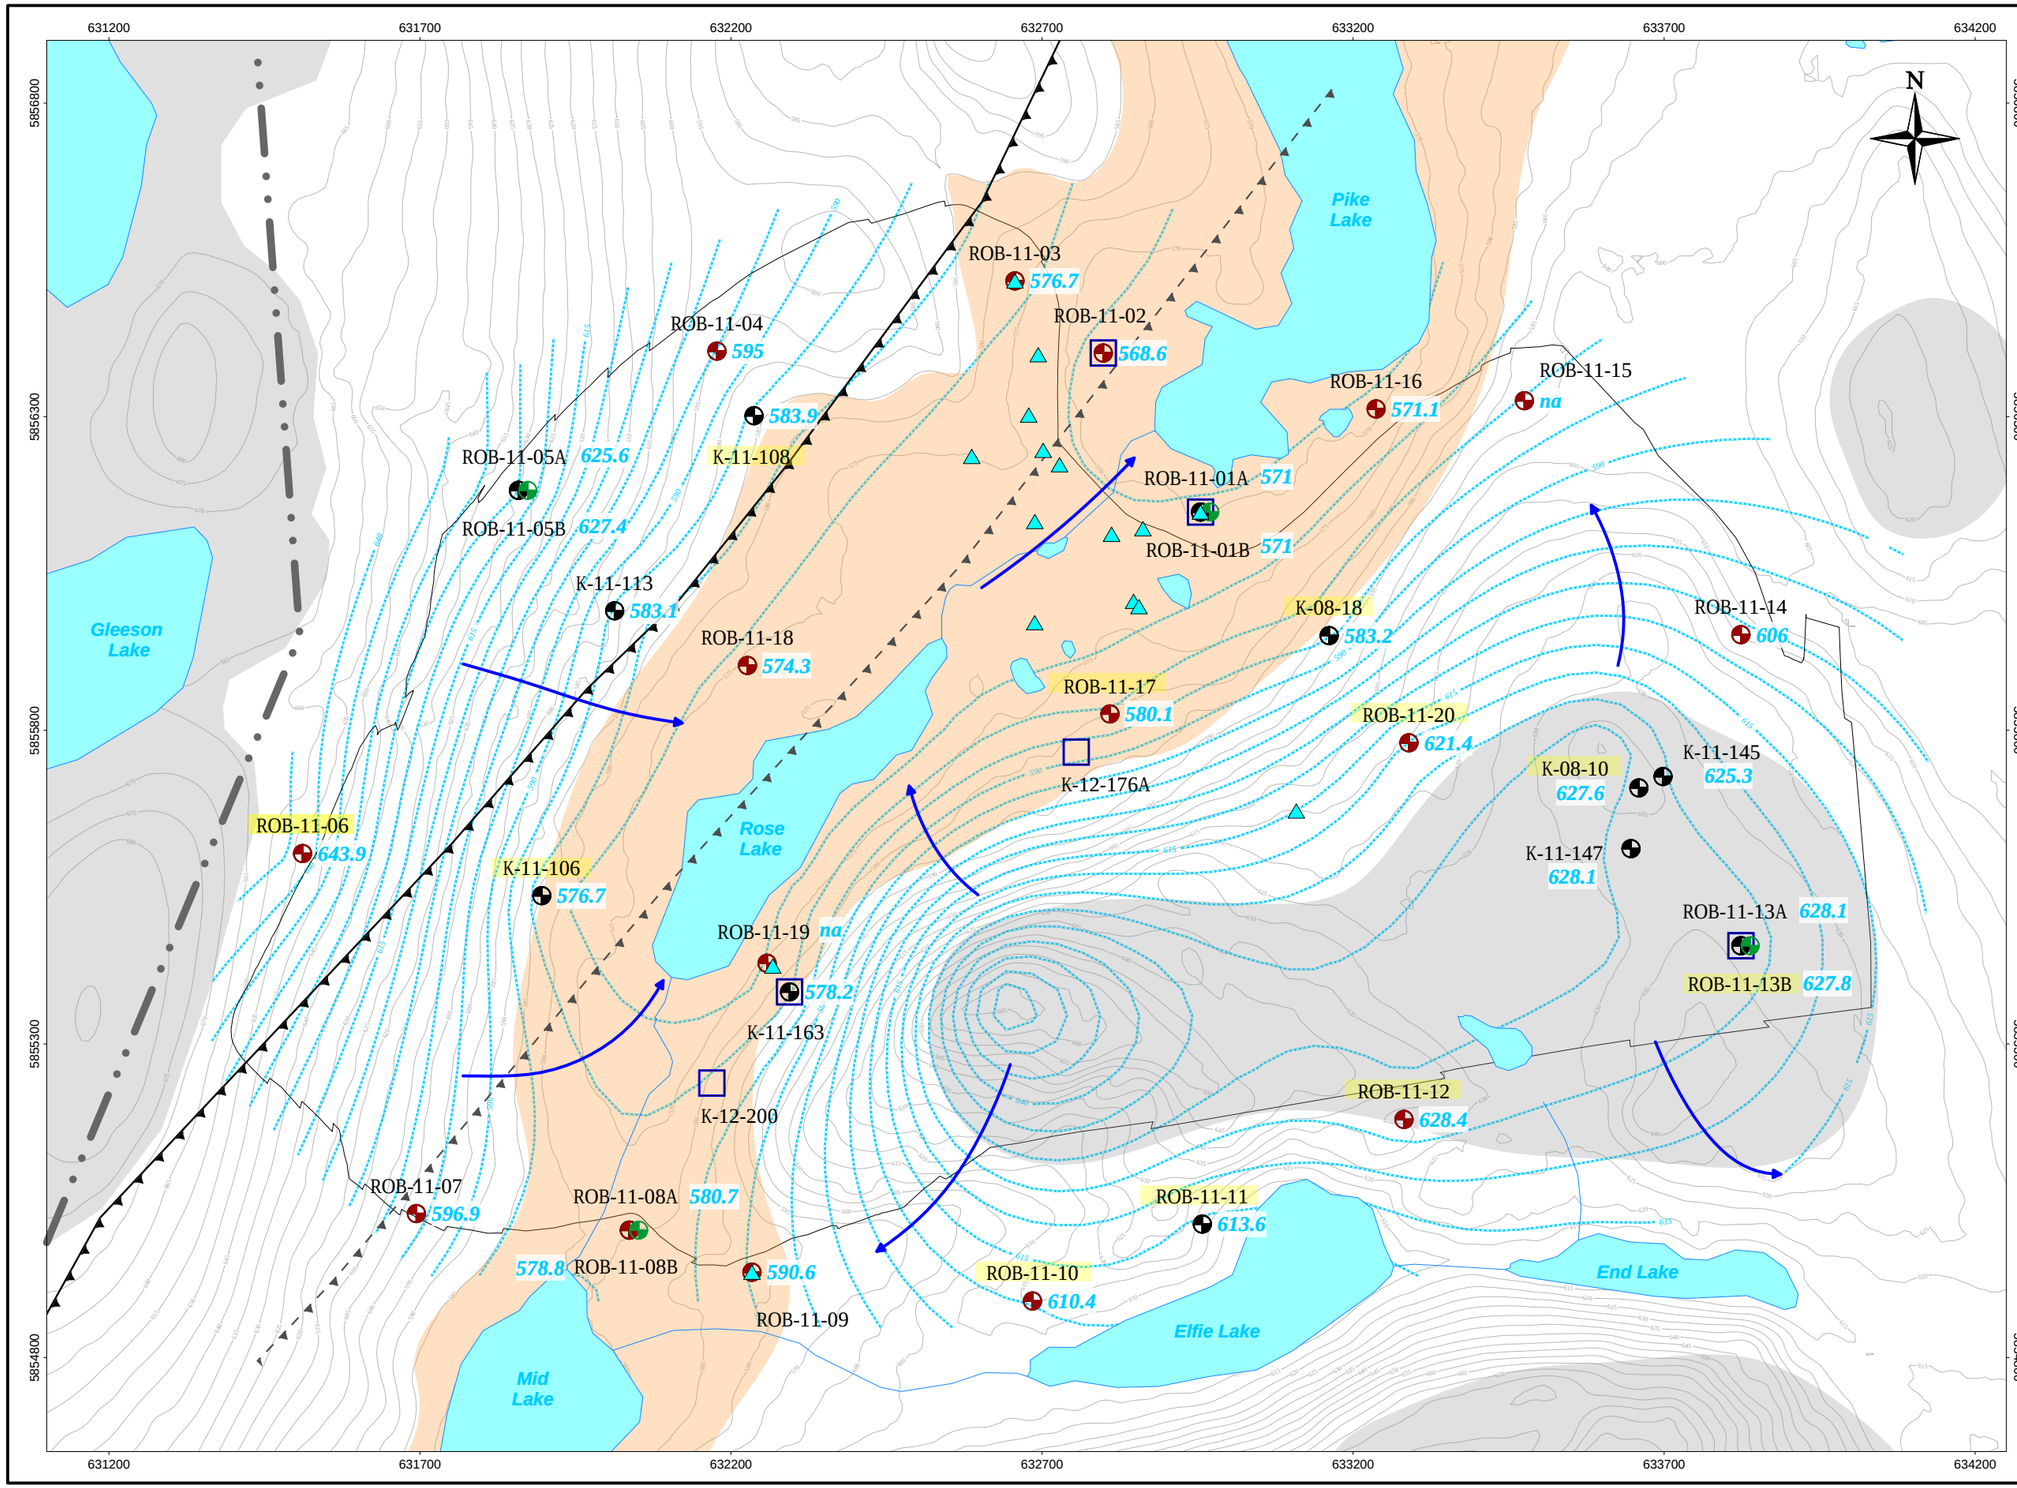
March 2024 AtkinsRéalis B-5



NOTES

Strong gradients are seen on slopes, in the bedrock, between K-08-10 and K-08-18 (0.08 m/m) and ROB-11-05A and K-11-113 (0.17 m/m). More gentle gradients were estimated in the center of the valley, at the till/bedrock interface, between ROB-11-07 and ROB-11-02 (0.02 m/m) and between ROB-11-04 and ROB-11-02 (0.03 m/m).

A vertical downwards gradient of 0.06 m/m was estimated at ROB-11-06A/B, in the western part of the pit, on a topographic high; vertical upwards gradients were estimated at ROB-11-08A/B (0.17 m/m) in the local discharge area in the valley center; and vertical upwards gradients were also estimated at ROB-11-13A/B (0.04 m/m) located on a topographic high in the eastern part of the pit.

During the May and September 2023 field investigations by SNCL, some exploration boreholes and wells showed artesian conditions. The presentation of artesian wells on the map is not exhaustive, as only certain areas were checked.

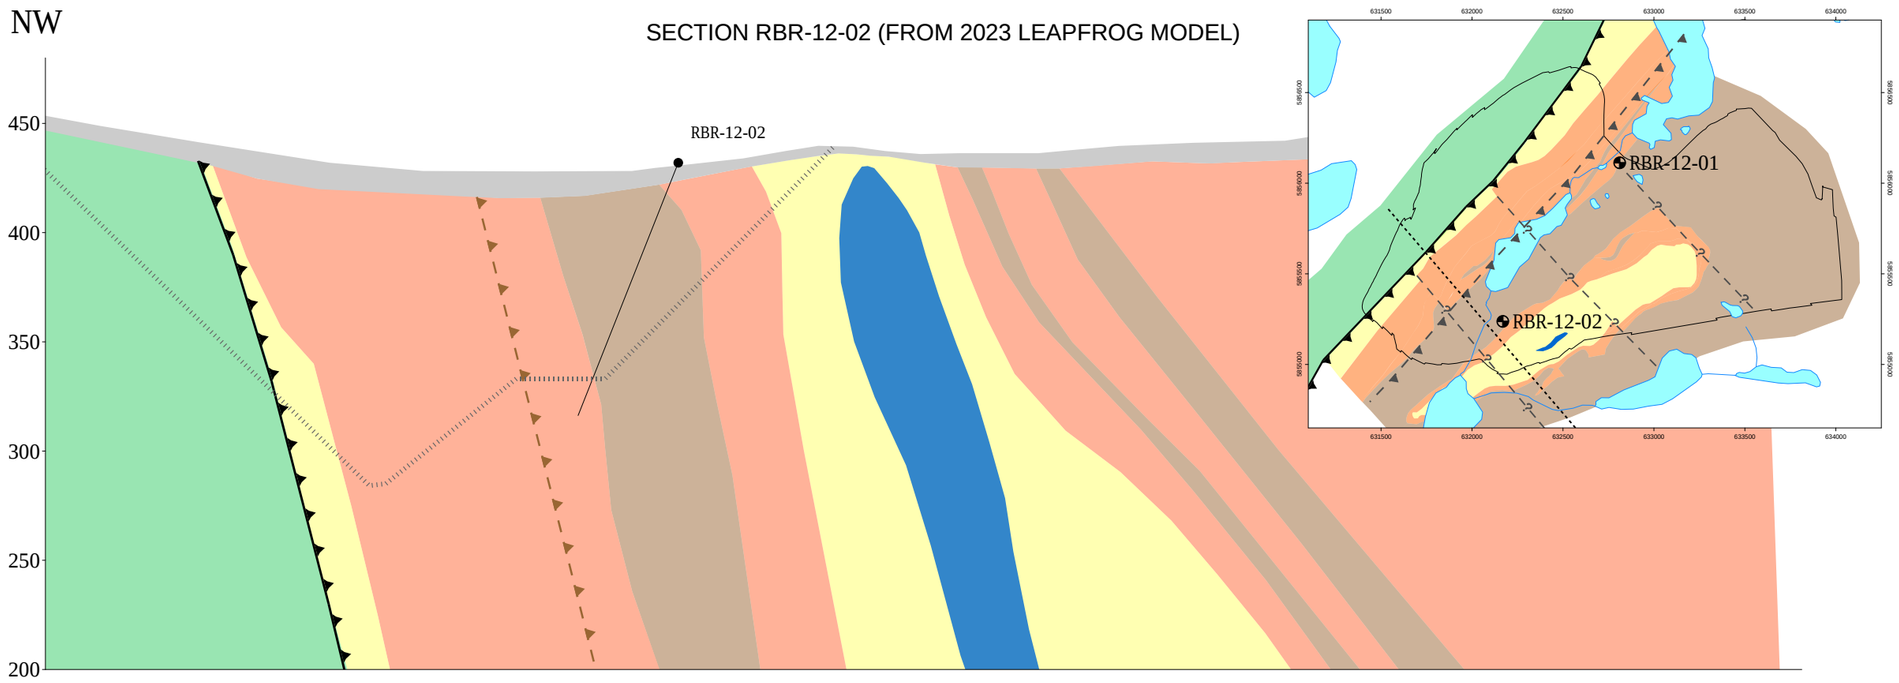
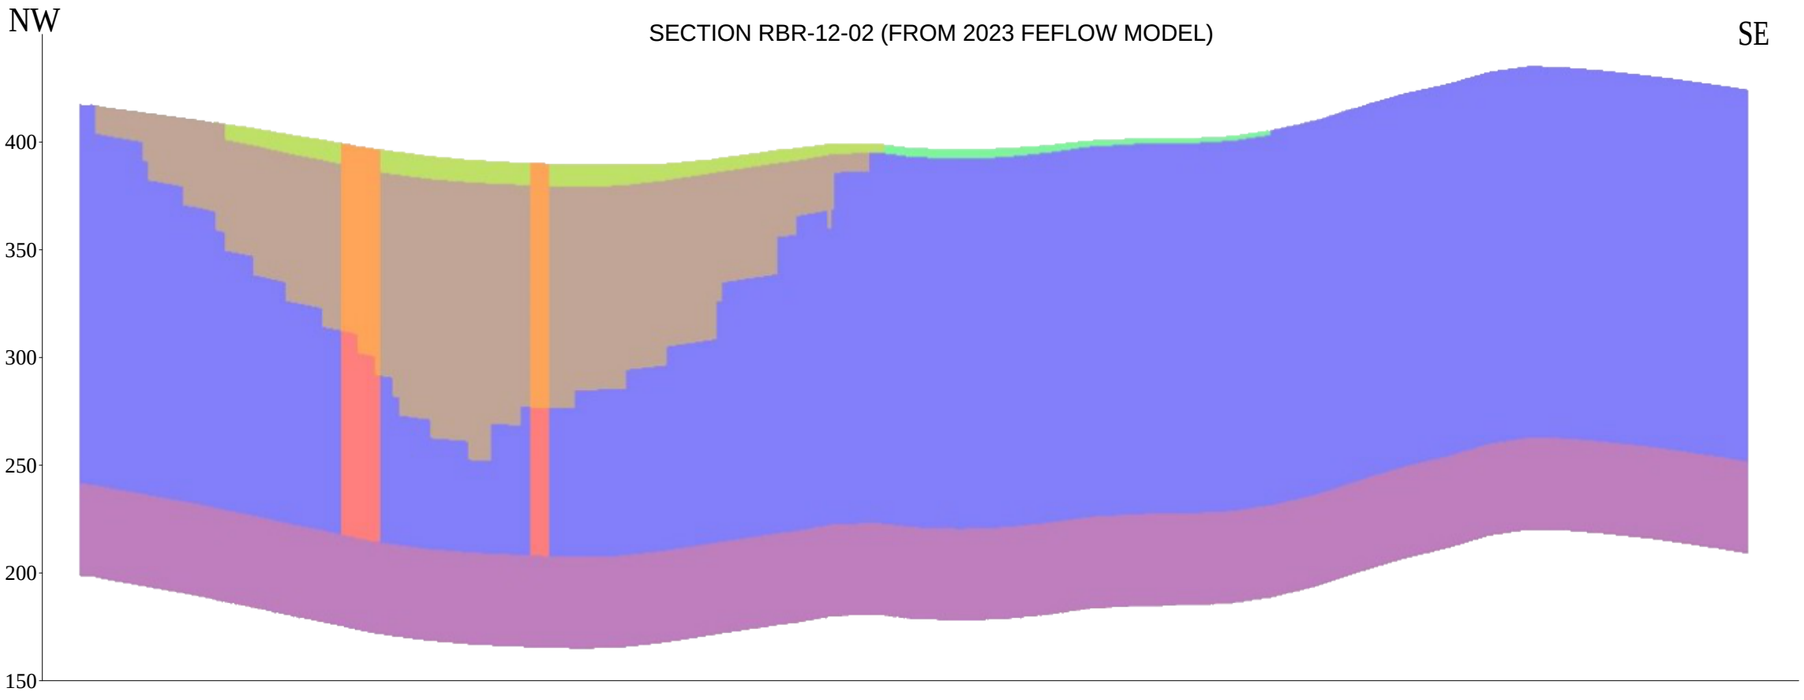
Geology from Geological Interpretation carried out by GMining (2023)

0 75 150 m

March 2024 AtkinsRéalis B-9





NOTES

Fault locations are approximative and fault continuity is uncertain outside Rose pit area.

A major thrust fault, parallel to the strike of the deposit, has been interpreted at the Wishart and Katsao Formation contact in the northwest portion of the North Rose deposit (Katsao-Wishart fault).

A second fault (or fractured zone) has been interpreted in the Sokoman Formation, in the center of the pit (Central fault).

BEDROCK GEOLOGY (LEAPFROG)

- OVERBURDEN — Till
- MENIHEK FORMATION — Mudstone and clastic flysh
- SOKOMAN FORMATION — Silicate-carbonate and oxide iron formation
- WISHART — Quartzite with local beds of muddy sediments
- DENAULT — Dolomite and calcitic marble
- KATSAO — Granite gneiss

HYDROSTRATIGRAPHY

Based on the geometric mean of measured data (slug tests & packer tests)

- OVERBURDEN (K = 1.2 x10^{-6} m/s)
- BEDROCK (K = 1.0 x10^{-7} m/s)
- DEEP BEDROCK (K = 1.0 x10^{-8} m/s)
- FAULT (K = 1.0 x10^{-5} m/s)

NOTES

Hydraulic conductivity zones shown in this figure are representative of slices 1 to 3 of the model. Below slice 3 is a zone of uniform bedrock (K = 5 x10^{-8} m/s) with the extension of the two faults at pit depth (slices 4 to 24). Below the pit is a zone of deep bedrock with a hydraulic conductivity of K = 1 x10^{-8} m/s (slices 24 to 28).

CALIBRATED HYDRAULIC CONDUCTIVITY

NOTES

Fault locations are approximative and fault continuity is uncertain outside Rose pit area.

Strong gradients are seen on slopes, in the bedrock, between K-08-10 and K-08-18 (0.08 m/m) and ROB-11-05A and K-11-113 (0.17 m/m). More gentle gradients were estimated in the center of the valley, at the till/bedrock interface, between ROB-11-07 and ROB-11-02 (0.02 m/m) and between ROB-11-04 and ROB-11-02 (0.03 m/m).

A vertical downwards gradient of 0.06 m/m was estimated at ROB-11-06A/B, in the western part of the pit, on a topographic high; vertical upwards gradients were estimated at ROB-11-08A/B (0.17 m/m) in the local discharge area in the valley center; and vertical upwards gradients were also estimated at ROB-11-13A/B (0.04 m/m) located on a topographic high in the eastern part of the pit.

NOTES

In a conservative approach, a selected scenario was represented assuming the faults were connected to the lakes and that their hydraulic conductivity ($5x10^{-5}$ m/s) was five times higher than the injection limit reached during packer tests.

It was also assumed that lake levels of Pike, Daviault, Molar and Mills would remain constant during dewatering operations.

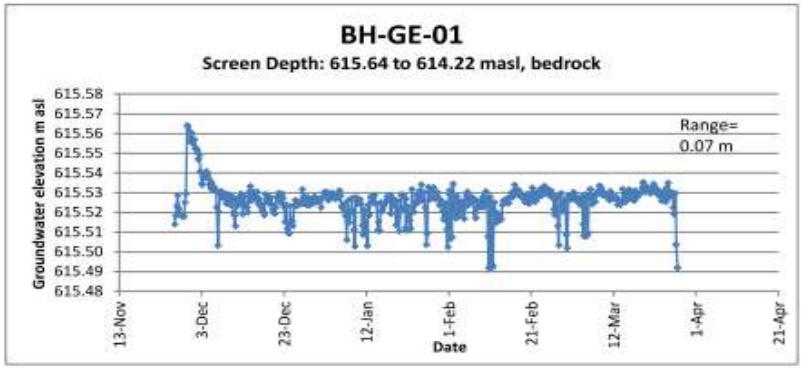
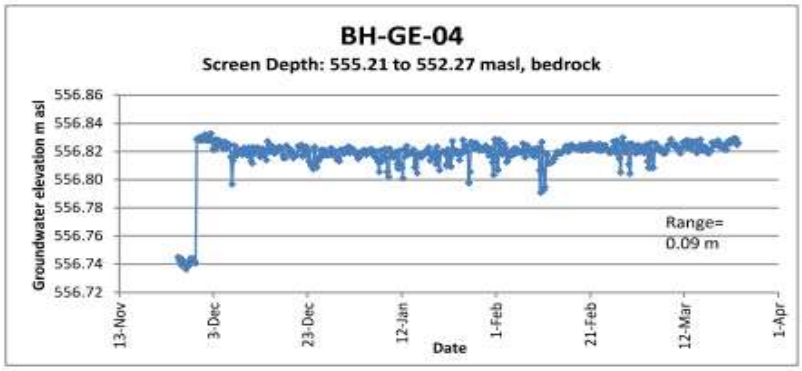
Appendix F. 2012 Pressure Transducers Data

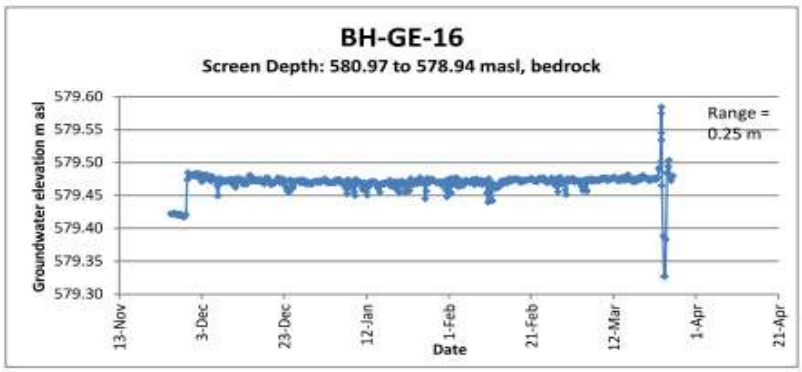
Appendix F - Pressure Transducers Data (from Stantec, 2012)
Pre-Feasibility Study of the Kamistiatusset (Kami) Iron Ore Property
Hydrogeology and Water Management



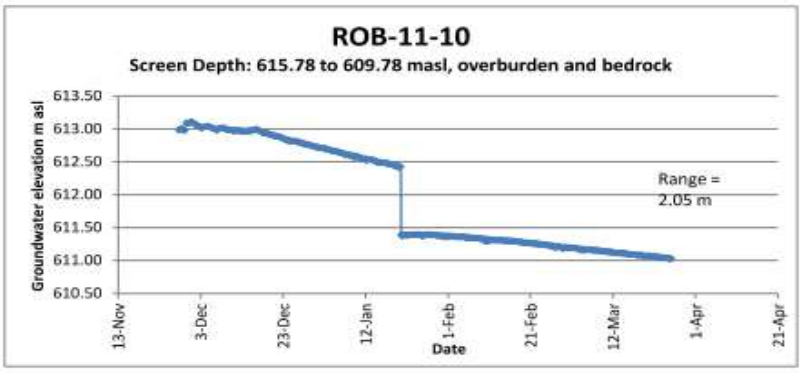
Logger is placed only 0.15 m below the top of the screen



Logger is placed about 1.5 m above the top of the screen

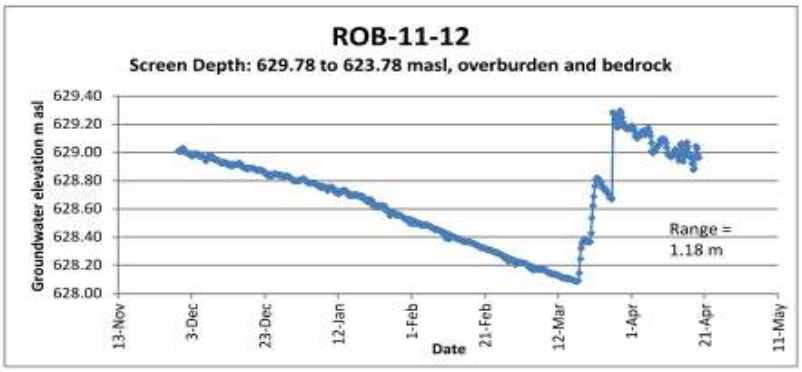


Logger is placed 1.5 m below the top of the screen



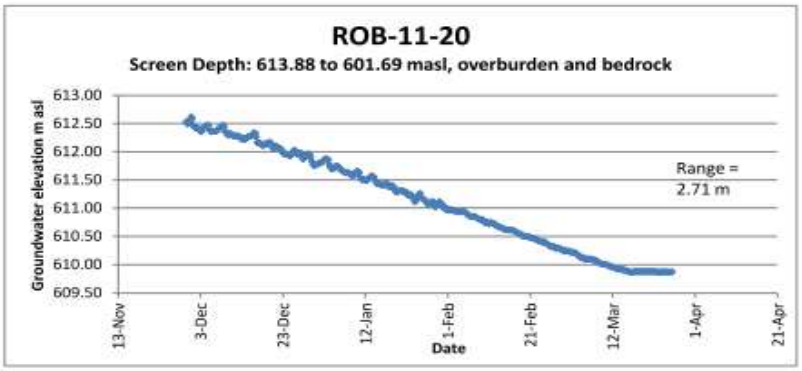
Logger is splaced about 5 m below the top of the screen

Sharp drop occurs after downloading logger data and replacing line



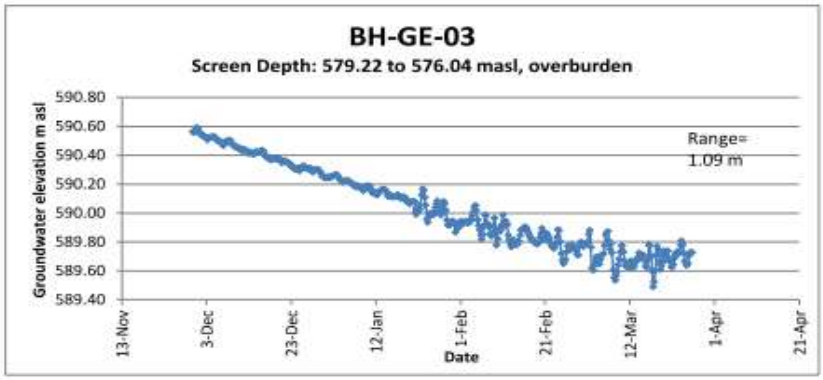
Logger is placed about 5.5 m below top of screen

Recharge could be due to a period of unseasonally warm temperatures causing early snow melt

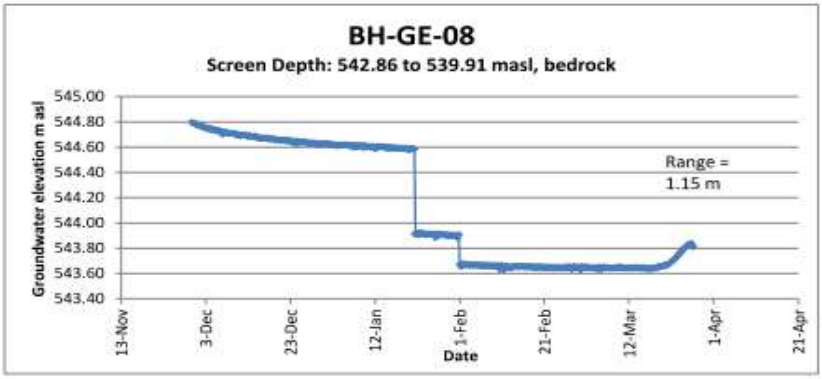


Logger is placed about 4 m below the top of the screen

Appendix F - Pressure Transducers Data (from Stantec, 2012)
Pre-Feasibility Study of the Kamistiatusset (Kami) Iron Ore Property
Hydrogeology and Water Management

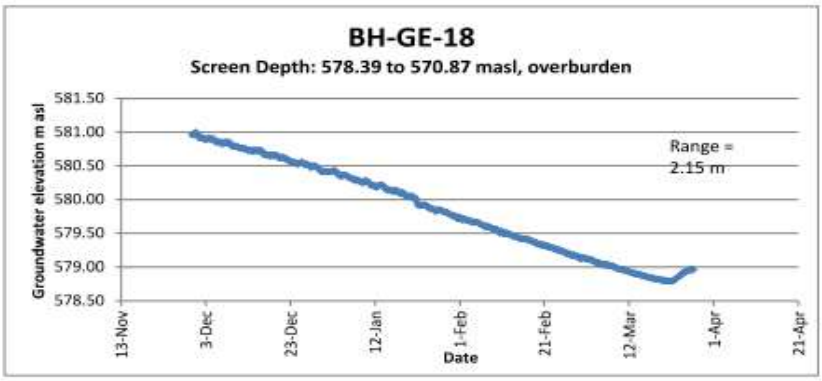


Logger is placed about 5 m above the top of the screen.



Recharge due to warm temperatures?

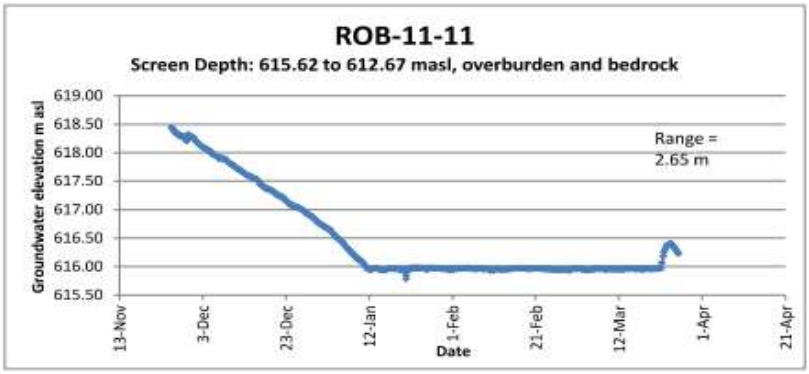
Logger is placed about 1.6 m below the top of the screen
The first drop corresponds to taking the logger out for downloading.



Logger is set at about 2.5 m below the top of the screen

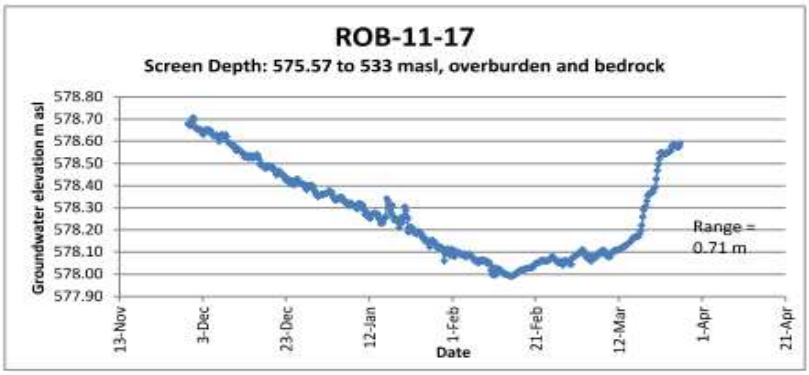
Recharge due to warm temperatures?

Appendix F - Pressure Transducers Data (from Stantec, 2012)
Pre-Feasibility Study of the Kamistiatusset (Kami) Iron Ore Property
Hydrogeology and Water Management



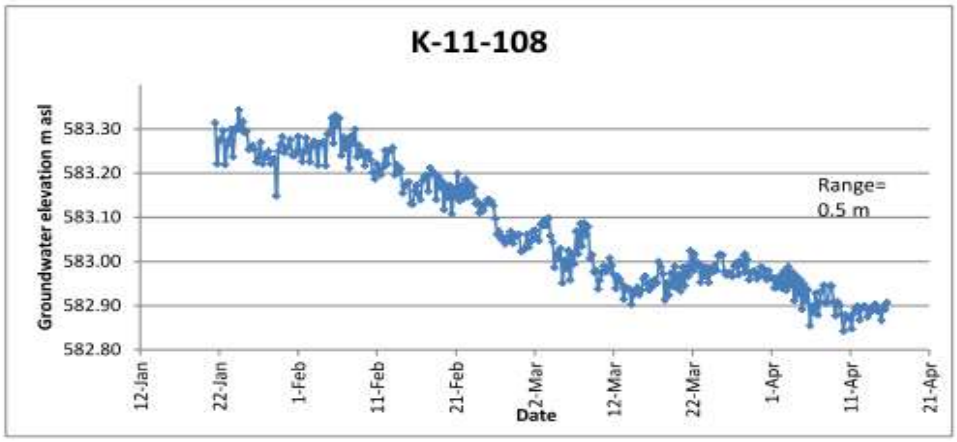
Logger is placed about 1 m below the top of the screen

Well very close to a lake, gw levels may have fallen until reaching equilibrium with

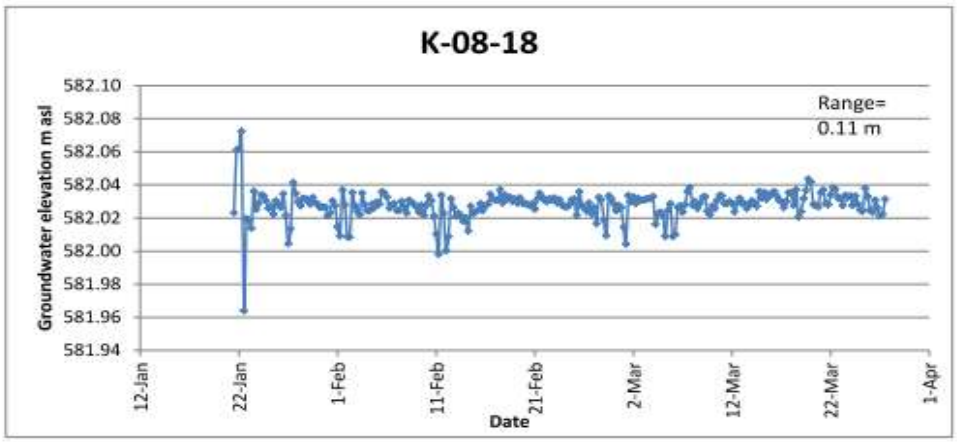


Logger is placed about 2 m belosw the top of the screen

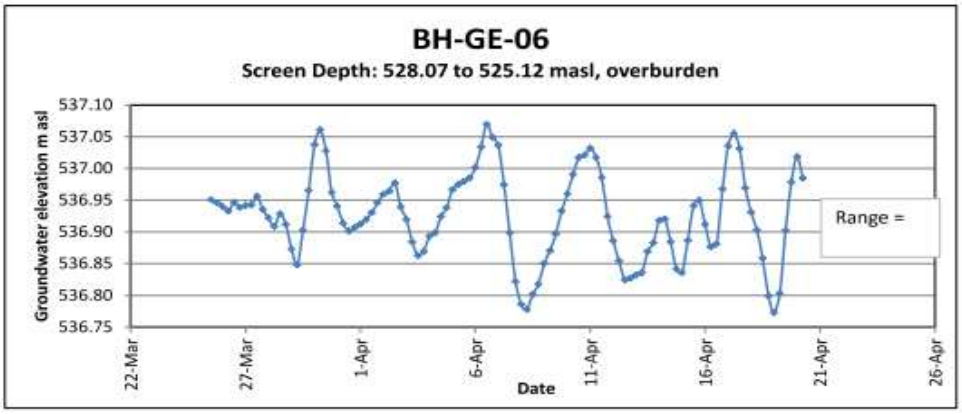
Recharge could be due to a period of unseasonally warm temperatures causing early snow melt



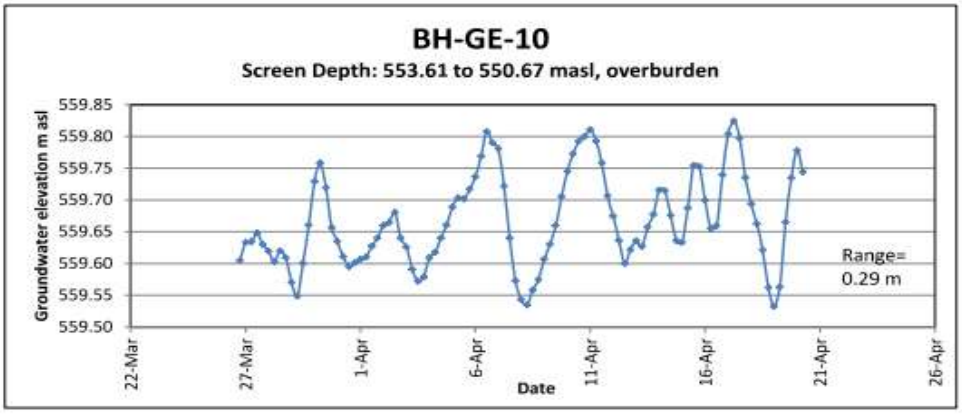
Don't have information on screen depth



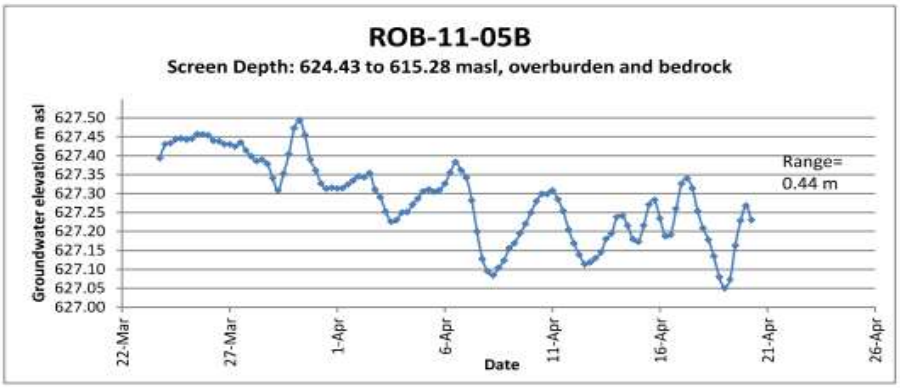
Don't have information on screen depth



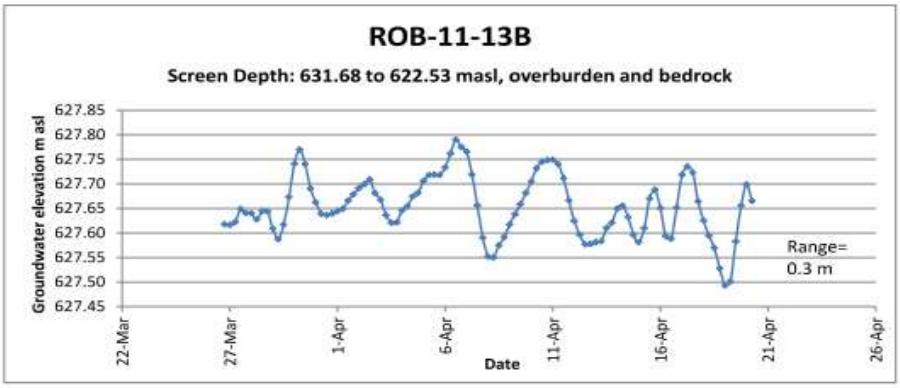
Logger is placed about 3 m above the top of the screen



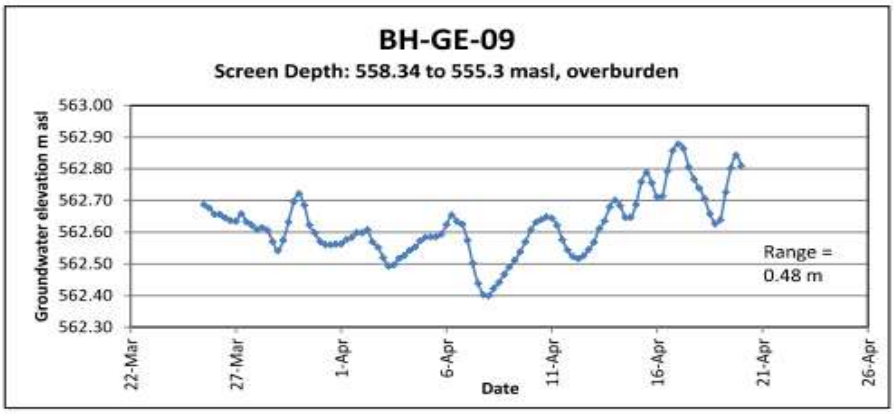
Logger is placed about 0.5 m below the top of the screen



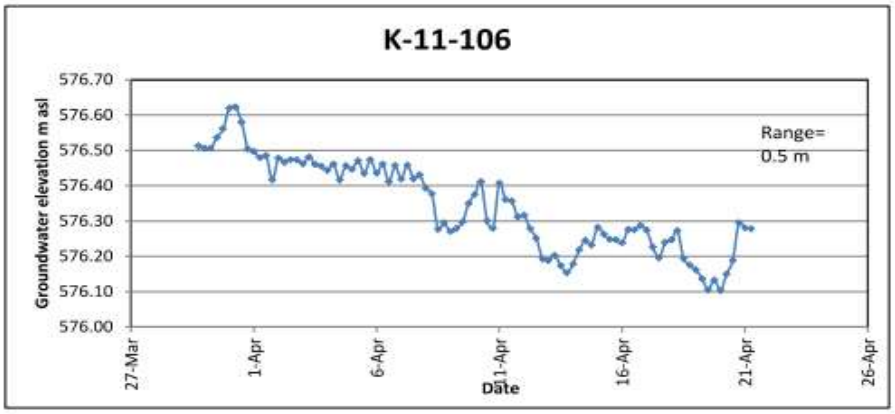
Logger is placed about 4 m below the top of the screen



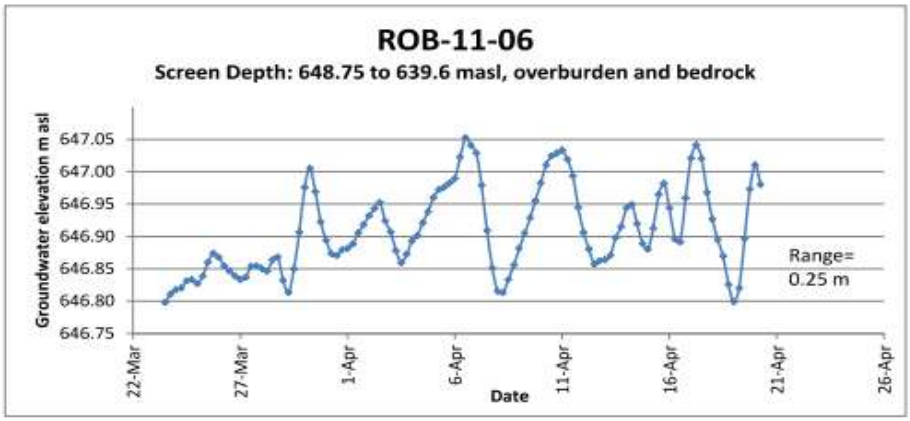
Logger is placed about 5.5 m below the top of the screen



Logger is placed 1.5 m below the top of the screen



No information on screen depths



Logger is placed about 7 m below the top of the screen

K-12-190	RBR-12-01	50.5	56	5.5	BC, Brittle. Extreme weathered.	Sokoman	SIF	SIF
K-12-190	RBR-12-01	56	58	2	BC, Brottle, vuggy. Weathered.	Sokoman	QCIF	CIF
K-12-190	RBR-12-01	58	59.5	1.5	Large size vugs in layuers. Low angle banding.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	59.5	68.8	9.3	Large intervals Qz diss Hm up to 50cm. Scattered Mt and VCG Hm laters or fracture filling. Low angle banding. Short transition to HIF.	Sokoman	LHMIF	M/HIF
K-12-190	RBR-12-01	68.8	82.5	13.7	BC, vuggy, Sand, weathered. High density banding up to 3cm at 25-35deg and large intervals up to 25cm Qz diss oriented xtls Hm. VCG secondary Hm on scattered narrow fractures. Seldom high grade Hm intervals up to 20cm at the beginning. Gradational transit	Sokoman	HIF	HIF
K-12-190	RBR-12-01	82.5	94.5	12	Strong weathered, BC, cleavage, vuggy layers. High density banding up to 5cm at 30-35deg. Large size vugs in layers. Seldom intervals Mt up to 35% and Hm up to 15%. Short transition to HIF.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	94.5	106.5	12	High density thin layers at the beginning and large intervals up to 15cm Qz/diss Hm at the end. Hm diss and VCG in scattered narrow fractures. Seldom sand intervals. Mt seldom thin layers. MIF from 1404.5 to 105. Short transition to MHIF.	Sokoman	HIF	HIF
K-12-190	RBR-12-01	106.5	110	3.5	Low angle banding and vuggy layuers up to 5cm at 40 to 50deg. BC and weathered. Mt/Hm diss within Qz and filling fractures up to CG.Short transition to MIF.	Sokoman	MHIF	M/HIF
K-12-190	RBR-12-01	110	121.5	11.5	Large intervals up to 30cm Qz diss Mt and vuggy layers. Hm +/- Mt filling narrow fractures. Hm diss increase to the end.Weathered and BC. Seldom white Qz lenses. Sharp ending.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	121.5	127.7	6.2	High density Mt thin layers up to 1cm at 35 to 50deg. Mt high density layers and diss related to Qz intervals.Scattered white Qz narrow lenses. 125.5m weathered HBGGN 3cm. Sharp transition to MIF.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	127.7	133.5	5.8	High density layers up to 2cm at 30-40cm. VFG Qz/Si/Mt. Verry competent core. Grunerite as silicate. Carb/Sil increase to the end up to 30%. Sharp ending.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	133.5	139	5.5	Banding up to 6cm at 40deg. Mt diss and thin layers. Carb in layers and oriented Xtls and spots. Hm diss in some Qz intervals. Sharp ending.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	139	145	6	Broken banding and banding up to 5cm at 40deg. Grunerite>>cumingtunite.	Sokoman	CSIF	SIF
K-12-190	RBR-12-01	145	148	3	Broken banding and banding up to 5cm at low angle up to 35deg. Advanced decarbonation. Grunerite>cumingtonite.	Sokoman	QCIF	CIF
K-12-190	RBR-12-01	148	154	6	Broken banding and banding up to 10cm at 30deg. Advanced decarbonation scattered intervals.	Sokoman	CSIF	SIF
K-12-190	RBR-12-01	154	158.2	4.2	Thin relict banding up to 0.5cm at 30deg. advanced decarbonation to complete replacement of carbonate. grunerite>>cumingtonite.Sharp ending in strong weatheredQCIF.	Sokoman	QSIF	SIF
K-12-190	RBR-12-01	158.2	160.2	2	Intense BC,weathered.	Sokoman	QCIF	CIF
K-12-190	RBR-12-01	160.2	173.5	13.3	Broken banding and banding up to 5cm at low angle up to 35deg. Carb>50% in some intervals. Carb/sil ratio different intervals. Moderate to advanced decarbonation. Sharp ending in weathered HBGGN.	Sokoman	QCIF	CIF
K-12-190	RBR-12-01	173.5	174	0.5	Weathered. Gar up to VCG.BC.	Post-Iron dyke/sill	HBG_GN	HBG_GN
K-12-190	RBR-12-01	174	181	7	Banding up to 6cm. Advanced decarbonation. Leached carb intervals. Qz/Sil-Carb ratio up to 2 in some intervals.Grunerite>>cumingtonite.	Sokoman	QSIF	SIF
K-12-190	RBR-12-01	181	182.3	1.3	Banding and broken banding up to 4cm at 35-40deg. Cleavage and fractured. Mt diss within qz banding. Advanced decarbonation at the end. Gradational transition to MIF.	Sokoman	LMQCIF	CIF
K-12-190	RBR-12-01	182.3	186.9	4.6	Banding and broken banding up to 5cm at 35-40deg. Cleavage and fractured, BC. Vuggy layers. Mt diss within Qz layers and seldom thin layers up to 2cm. Scaterred Pyrite on thin fractures. Short transition to MIF.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	186.9	190.7	3.8	From banding to broken banding and tight folded up to 6cm at 30 to 40deg. Cleavage, sand and vuggy layers. Mt diss large intervals up to 20cm and thin layers. Transitional To MSIF.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	190.7	198.4	7.7	Banding to wavy banding at 40 deg. Mt is disseminated up to FG or in layers up to 1 cm related to silicates/carbonates layers. Fibrous mineral at the end. Short transitional to HMIF.	Sokoman	MSIF	SIF
K-12-190	RBR-12-01	198.4	200	1.6	Banding to wavy and tight folded bands. White qz lences and boudinage. Hm up to MG in wavy layers related to fibrous min. Sharp ending in MIF.	Sokoman	HMIF	M/HIF
K-12-190	RBR-12-01	200	215	15	Banding to broken banding and boudinage. Mt diss oriented xtls and thin layers up to 1cm. Sil up to 20% in some intervals. High density layers at the end. Gradational transition.	Sokoman	MIF	MIF
K-12-190	RBR-12-01	215	224	9	Broken banding, wavy, tight folding and banding up to 5cm at 35-45deg. Scattered verry narrow HBGGN up to 3cm. Scattered vuggy layers. Mt oriented xtls and thin layers. Sharp ending in qz/mt sand. Lost hole.	Sokoman	MSIF	SIF

HOLEID	ID	From (m)	To (m)	Length (m)	Lithology Description	Formation	Rock Type	Rock Type Grouped
K-12-194	RBR-12-02	0	16	16		MISC	OB	OVB
K-12-194	RBR-12-02	16	23	7	Extreme BC. Silic weathered to Chlorite. Missing core. Lithology from fragments.	Sokoman	SIF	SIF
K-12-194	RBR-12-02	23	25	2	Relict banding up to 5cm at 45deg. Incipient decarbonation. Short transition to SIF.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	25	34	9	Fractured, BC relict banding. Strong weathered intervals. No pattern texture. Patches of grunerite +/- cumingtonite, dolomite and qz following a relict banding. Ch on fr and joints. Short transition to QCIF.	Sokoman	SIF	SIF
K-12-194	RBR-12-02	34	38.6	4.6	Relict banding and banding up to 4cm at 50-60deg. Sil up to 50% , 60cm interval. Sil 90% replaced by Chlorite. Fractured. Breciated. BC intervals. Sharp ending in a narrow HBGGN.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	38.6	42	3.4	!0cm HBGGN at the beginning. Ga up to 1cm disseminated. Several narrow HBGGN up to 10cm.	Menihek Fm (HW)	GF_B_MS_SCH	SCH
K-12-194	RBR-12-02	42	54.5	12.5	Several HBGGN intervals up to 50cm. Scattred Gf. Slickensided. Chlorite on cleavage. Sharp ending in QCIF.	Menihek Fm (HW)	B_MS_SCH	SCH
K-12-194	RBR-12-02	54.5	55.7	1.2	Banding at 50deg. Chlorite an silicates.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	55.7	62	6.3	Several HBGGN intervals up to 80cm with GA diss up to 0.5cm. Chlorite weathering related to HBGGN.	Menihek Fm (HW)	B_MS_SCH	SCH
K-12-194	RBR-12-02	62	64.5	2.5	Ga aligned xtls up to 0.2mm. Several Bi-Ms-Qz schist intervals up to 30cm. Sharp ending.	Post-Iron dyke/sill	HBG_GN	HBG_GN
K-12-194	RBR-12-02	64.5	66.6	2.1	Very fine grain. Scattered thin qz layers. Short Gf intervals sevage. Sharp ending.	Menihek Fm (HW)	B_MS_SCH	SCH
K-12-194	RBR-12-02	66.6	69	2.4	FG to MG grain size. Scattered thin qz layers. Sharp ending.	Post-Iron dyke/sill	HBG_GN	HBG_GN
K-12-194	RBR-12-02	69	85.5	16.5	FG to MG grain size. Few GF-BI-MS-QZ schist intervals up to 40cm. Scattered Qz thin layers. Gradational ending.	Post-Iron dyke/sill	HBG_GN	HBG_GN
K-12-194	RBR-12-02	85.5	86.8	1.3	FG grain size. Several low GA diss intervals. Seldom Qz thin layers. Sharp ending.	Menihek Fm (HW)	B_MS_SCH	SCH
K-12-194	RBR-12-02	86.8	91	4.2	Ga oriented xtls in layers. FG to MG grain size. Sharp ending.	Post-Iron dyke/sill	HBG_GN	HBG_GN
K-12-194	RBR-12-02	91	97	6	FG grain size. Ga diss up to HBGGN composition in several intervals. Scattered Qz thin layers. GF schist narrow layers up to 10cm.Short transition to HBGGN.	Menihek Fm (HW)	B_MS_SCH	SCH
K-12-194	RBR-12-02	97	101.8	4.8	FG to MG grain size. From 100 to 101.8 Large GF schist intervals up to 50cm, and Ga xtls up to 1cm. Broken to brecciated at the nend. Sharp ending.	Post-Iron dyke/sill	HBG_GN	HBG_GN
K-12-194	RBR-12-02	101.8	111.5	9.7	Several short Gf schist intervals. Slickensides and BC first 5m. VFG to FG grain size.	Menihek Fm (HW)	B_MS_SCH	SCH
K-12-194	RBR-12-02	111.5	121	9.5	Foliated to 40deg. Scattered narrow Gf intervals.Seldom low grade Ga diss intervals. Sharp ending in GF schist and then QCIF.	Menihek Fm (HW)	MS_B_SCH	SCH
K-12-194	RBR-12-02	121	121.5	0.5		Menihek Fm (HW)	GF_B_MS_SCH	SCH
K-12-194	RBR-12-02	121.5	122.7	1.2	Narrow HBGGN up to 5cm at the beginning and almost every 10cm. Sharp ending.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	122.7	134.3	11.6	Several Gf schist and HBGGN intervals up to 50cm.	Menihek Fm (HW)	MS_B_SCH	SCH
K-12-194	RBR-12-02	134.3	143.5	9.2	High Ms content. Gf low grade pervasive and seldom narrow bands medium grade.Several Ga diss intervals. Fractured along core at the end. CG Qz lenses at the end. Sharp ending.	Menihek Fm (HW)	GF_B_MS_SCH	SCH
K-12-194	RBR-12-02	143.5	144.3	0.8	Pegmatitic CG QZ and Ms alternating with Ms schist. Scattered sulphide filling thin fractures. Sharp ending.	Menihek Fm (HW)	MS_SCH	SCH
K-12-194	RBR-12-02	144.3	162.1	17.8	Seldom narrow CG Qz lenses at the beginning. GF schist up to 30cm intervals at the beginning. Sharp ending.	Menihek Fm (HW)	MS_SCH	SCH
K-12-194	RBR-12-02	162.1	169.1	7	FG up to MG Ga in layers up to 25%. Short GF interval at the beginning. Scattered thin Qz layers. Sharp ending.	Menihek Fm (HW)	HBG_GN-Menihek	HBG_GN
K-12-194	RBR-12-02	169.1	185.5	16.4	HBGGN-Gf sch-Bi&Ms sch alternating large intervals.Strong wethered intervals at the beginning and intense weathered from 177.5m to the end.	Menihek Fm (HW)	GF_B_MS_SCH	SCH
K-12-194	RBR-12-02	185.5	194	8.5	Extreme weathered. Large BC and gauge intervals. Sharp ending in Gf schist.	Menihek Fm (HW)	MS_SCH	SCH
K-12-194	RBR-12-02	194	200.2	6.2	50cm high Gf at the beginning. Weathered, BC, brittle. Sharp ending.	Menihek Fm (HW)	HBG_GN-Menihek	HBG_GN
K-12-194	RBR-12-02	200.2	214.6	14.4	Broken banding, wavy and banding up to 5cm at 50deg. Carb up to 50% at the end. Advanced decarbonation. Fractured. Strong weathered at the edges. Sharp ending.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	214.6	218	3.4	Gf content. Ga up to 2cm in layers. Moderate weathered and BC. Low angle schistosity up to 45deg.	Menihek Fm (HW)	HBG_GN-Menihek	HBG_GN
K-12-194	RBR-12-02	218	219.3	1.3	White Qz lenses up to 20cm aty low angle and HBGGN narrow intervals. HBGGN made up from Ga&Qz intervals.	Menihek Fm (HW)	HBG_GN-Menihek	HBG_GN
K-12-194	RBR-12-02	219.3	223.7	4.4	Ga up to 20% in layers. Gf rich intervals. Possible MS_BI schist with Ga.Sharp ending.	Menihek Fm (HW)	HBG_GN-Menihek	HBG_GN
K-12-194	RBR-12-02	223.7	227	3.3	High density layers up to 3cm at 50deg. Silicates extreme weathered in Chlorite. Mt diss and thin layers.	Sokoman	MIF	MIF

HOLEID	ID	From (m)	To (m)	Length (m)	Lithology Description	Formation	Rock Type	Rock Type Grouped
K-12-194	RBR-12-02	227	231.8	4.8	HBGGN/SIF/Gf schist alternating intervals up to 50cm. Weathered and BC. Sharp ending.	Post-Iron dyke/sill	HBG_GN	HBG_GN
K-12-194	RBR-12-02	231.8	245.5	13.7	Extreme weathered. Cb complete leached out. Vuggy layers. BC. Qz up to 90% intervals. Gradational transition.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	245.5	250	4.5	Extreme BC. Missing core, poor recovery. Vuggy layers. Sand intervals. Lithology reconstitute from fragments. Gradational trensition.	Sokoman	QZT	QZT
K-12-194	RBR-12-02	250	254.8	4.8	Alternating of Qz and MS-Qz schist. Weathered, BC, brittle. Poor recovery. Sand intervals. Sharp ending.	Sokoman	QZT	QZT
K-12-194	RBR-12-02	254.8	258.4	3.6	Weathered, brittle. Sharp ending.	Menihek Fm (HW)	MS_SCH	SCH
K-12-194	RBR-12-02	258.4	265.7	7.3	Relict banding up to 5cm at 50deg. High density vuggy layers up to 2cm. Weathered and BC. Scattered Mt thin layers, weathered to Goetite. Sharp ending.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	265.7	268	2.3	Moderate density layers up to 4cm at 50deg. Vuggy layers. Mt diss within Qz layers. BC on cleavage. MS traces filling vugs. Short transition to QCIF.	Sokoman	LMIF	MIF
K-12-194	RBR-12-02	268	292	24	Broken banding and banding up to 5cm at 50deg. Vuggy and porous bands. Silicates increase to the end. Disseminated within Qz bands a soft, gray matalic mineral up to 5%. Bluish-gray streak?!?!?! BC intervals.Thinup to 5cm scattered HBGGN.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	292	295	3	Fault zone. Extreme BC. Missing core. Sand&clay intervals. Weathered.	Sokoman	QZT	QZT
K-12-194	RBR-12-02	295	298.7	3.7	Several relict banding intervals at 50deg. Unknow gray min diss up to 5% in some intervals. BC intervals. Gradational ending.	Sokoman	QCIF	CIF
K-12-194	RBR-12-02	298.7	300	1.3	Banding up to 3cm at 50deg. High density layers. Advanced decarbonation. EOH.	Sokoman	QSIF	SIF

225	573.2	- Planar upper boundary approximately 35° to core axis (parallel to J1) - Artesian flow rate increases upon intersection of seam. - Bottom 27 m of drill rods fill with sand material and hole is abandoned. End of Borehole - Hole abandoned at approximately 224.0 m depth along borehole in decomposed/crushed seam to avoid risk of losing drill rods. - Flowing artesian conditions encountered in bedrock. Artesian flow rate increases upon intersection of sand seam at 223.7 m depth along hole.

1. Introduction

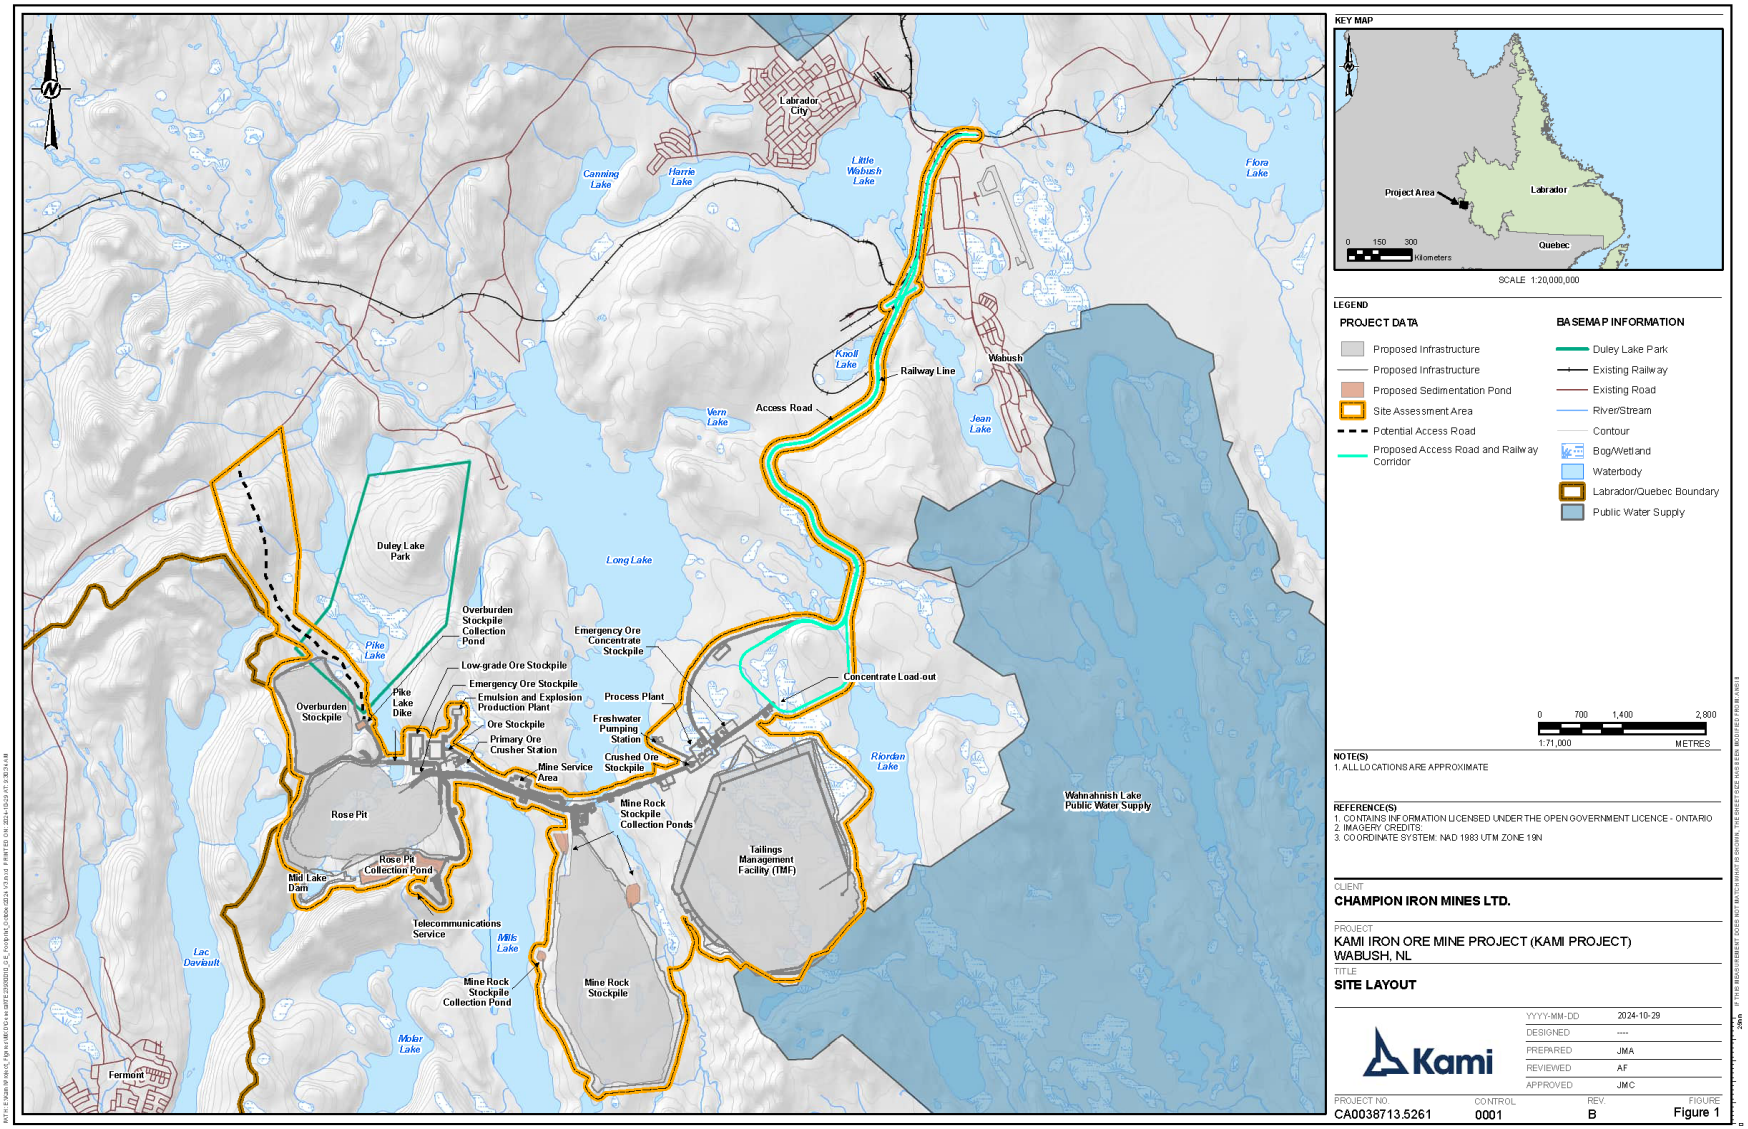
CHAMPION IRON

1. Introduction

Champion Iron Mines Ltd (Champion) is proposing to construct and operate the Kamistiatusset (Kami) Iron Mine Ore Project (the Project), a high-grade iron ore project located in the Province of Newfoundland and Labrador. The Project site is located entirely in Labrador, approximately 7 km southwest of the Town of Wabush and 5 km northeast of the Town of Fermont, Québec (Figure 1-1).

The Project will involve the construction, operation and closure of an open pit iron ore mine and supporting infrastructure, including overburden stockpile (OSP), mine rock storage facility, tailings management facility (TMF), process plant, and associated water management facilities (WSP, 2024a). Lorax Environmental Services Ltd. (Lorax) was retained by Champion to inform ongoing Project refinement as it pertains to water balance and water quality. This report documents the development and results of the site-wide water balance and water quality model (WBWQM) constructed by Lorax. The primary modelling objective is the prediction of water volume and solute transfers within the mine site and to the receiving environment during all phases and periods of the Project (WSP, 2024a). The WBWQM results are intended to inform design, refinement, and adaptive management decision making and assessment in support of the Environmental Impact Statement (EIS) for the Project.

Figure 1-1: Kami Iron Ore Project



Modified from WSP, 2024a.

2. Water Balance and Water Quality Model

CHAMPION IRON

2. Water Balance and Water Quality Model

A site-wide WBWQM has been developed to represent Construction, Operations, Closure phases, and Post-closure period of the Project (Table 2-1).

Table 2-1: Project Phases and Periods

Project Phase/Period	Project Year	Description
Construction phase	Year -1	Development of mine facilities
Operation phase	Years 0 through 24	Mining and processing
Closure phase	Years 25 through 36	Active flooding of the pit
Post-closure period	Years 37 through 73	Re-establishment of passive surface water drainage following the pit flooding as well as recontouring and revegetating disturbed areas

The WBWQM was constructed in GoldSim (version 15.0), a versatile and flexible platform developed by the GoldSim Technology Group and well suited for visualizing and simulating dynamic systems such as mine site water and load (water quality) balances. Flows and constituent loads are represented in GoldSim using:

- **data elements**—constant or time-dependent scalar and vector quantities
- **expressions**—mathematical formulas linking flow elements
- **reservoirs**—finite (or infinite) volume storage facilities with user-specified addition, withdrawal, and leakage rates
- **flow logic**—programming commands that allow flow splitting, assignment of priorities, allocations, and/or demands

Elements are assembled and connected in GoldSim using an intuitive graphical user interface. Unit conversion is handled automatically between elements, and automated error checking is invoked during model simulations to help ensure unit and logical consistency between calculations.

2.1 Water Balance

This section presents the inputs and assumptions in the assembly and running of the site-wide water balance model (WBM). Briefly, the guiding assumptions are listed here:

- The WBM produces monthly discharge data for the Project site for two conditions: pre-mine (*i.e.*, pre-development, natural case) and base case (*i.e.*, with Project). The pre-mine module of the WBM considers no mine area footprints and/or water-

related management activities, whereas the base case module of the WBM has mine plan and water management activities with the Project fully encoded.

  - This approach allows for a direct comparison to be made between the current and undistrubed flow regime and the predicted mine-affected flow regime, for any location and/or time period of interest, over the entire model domain and the full Project lifespan (Construction phase through Post-closure period).

Given the highly dynamic nature of streamflow at the Project site and the potential for upset conditions (*e.g.,* high-magnitude rainfall events, rapid freshet) to occur on sub-monthly time scales and the operational necessity of managing mine contact waters daily, the WBM is set up to run on a daily time step.

- This was made possible by the availability of regional daily climate and streamflow data that the WBM is driven by and calibrated to, respectively. All WBM runs were completed at a daily time step with flow outputs from the WBM aggregated to a monthly average time step.
- Climate data used to drive the site-wide WBM were adjusted to account for potential future climate change. As decribed in Section 2.1.4.4, the 40-year climate data record was looped two times (*i.e*., 78-year record to represent calendar years 2023 through 2100), then adjusted for temperature and precipitation increases forecast by the Shared Socioeconomic Pathway 2-4.5 (SSP2-4.5) climate change scenario.
- The pre-mine module of the WBM, and many of the mine sub-catchments within the base case module generate run-off from climate data with a calibrated watershed model, as decribed in Section 2.1.5.
- Mine facilities are assumed to develop according to the development schedules and timelines set out in the mine plan, as described in Section 2.1.6.

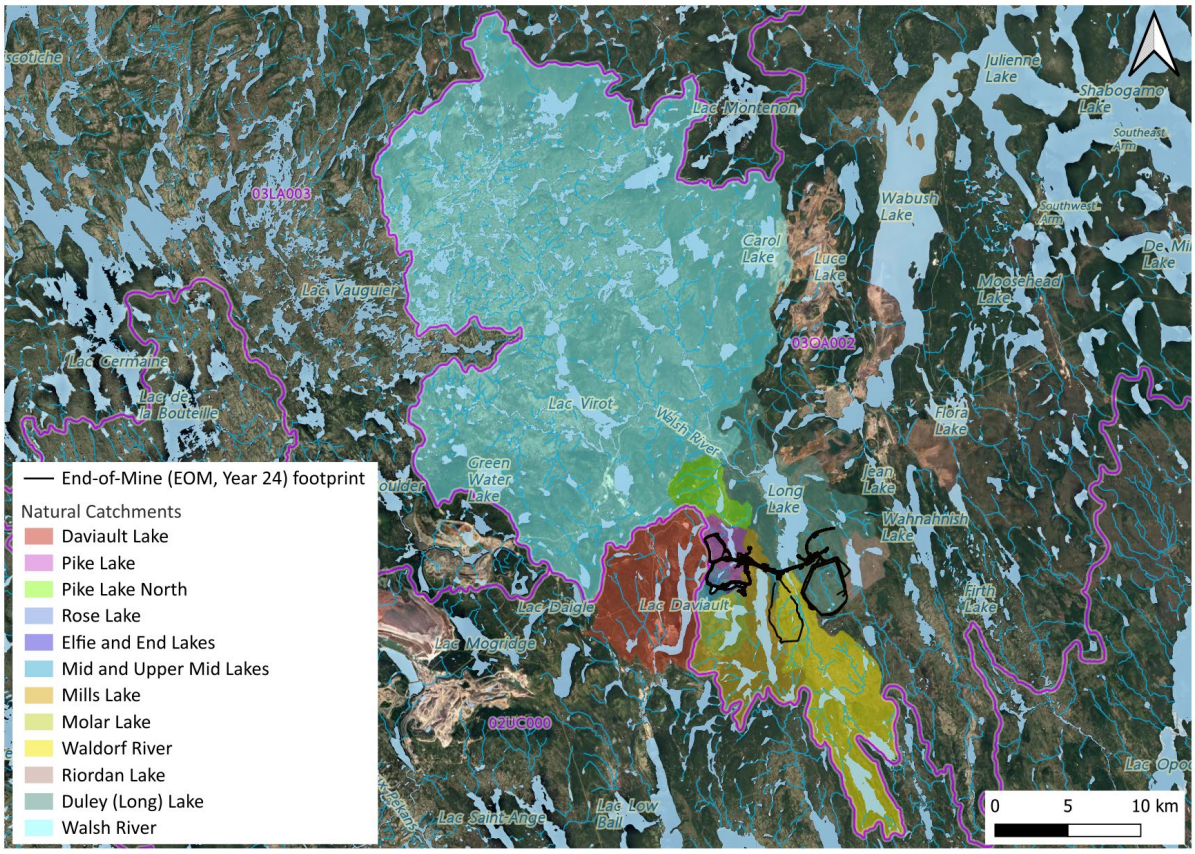
The WBM represents the interaction of the local climatic and streamflow regimes with Project facilities and associated water management infrastructure. The model simulates the volumes of various water types (*i.e*., non-contact and surface contact) based on these interactions to inform water management decision-making.

2.1.1 Setting

Natural catchments surround the Project area with drainage directions generally towards the north and east through a series of lakes, wetlands, and rivers that form the headwaters of the Churchill River catchment (Figure 2-1). The west side of the Project drains through the Pike Lake and Pike Lake North catchments north to the Walsh River, which flows to

the Duley Lake (formerly Long Lake) outlet. Mills Lake, Waldorf River, and Riordan Lake, which are located south and southwest of the Project, also flow into Duley Lake. Daviault Lake, located in Québec, does not have any surface water connection with the Project, but it is predicted to have a degree of groundwater seepage into the pit. Rectangle Lake, situated south of the Duley Lake catchment and east of the Waldorf River catchment, has no surface or groundwater connection to the Project; however, it is predicted to receive seepage from the TMF during the Post-closure period.

Figure 2-1: End-of-Mine (Year 24) Footprint in Relation to Natural Catchments within the Project Area



Mine facilities included in the Kami WBWQM are the Rose Pit, OSP, mine rock stockpile (MRS), TMF, process plant, and associated water management facilities (Pit collection pond, MRS collection ponds, OSP collection pond, retention basins).

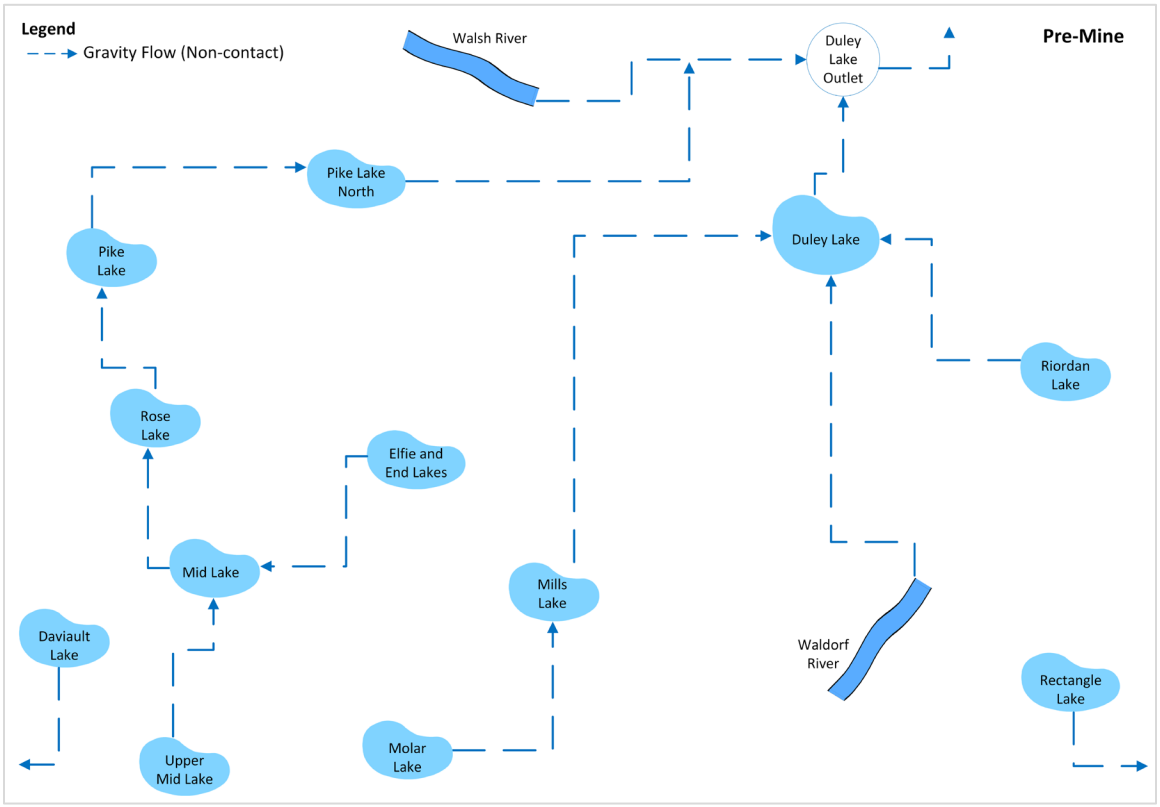
2.1.2 Model Architecture

Conceptual models showing the pre-mine natural catchment setting and the interactions of the Project facilities during the Construction, Operations, and Closure phases, and Post-closure period are presented in Figure 2-2 to Figure 2-7. The flow arrows show the direction, and the type of flow, accounted in the WBWQM.

2.1.2.1 *Pre-mine Conditions*

Under current pre-mine conditions (Figure 2-2), Duley Lake receives inflows from Riordan Lake, Waldorf River, and Mills Lake, with Mills Lake receiving inflows from Molar Lake (Figure 2-2). Duley Lake then discharges through the Duley Lake outlet. Elfie Lake, End Lake, and Upper Mid Lake drain into Mid Lake, which then flows into Rose Lake. Rose Lake feeds into Pike Lake, which flows into Pike Lake North. Pike Lake North then discharges into Walsh River, which ultimately flows into the Duley Lake outlet. Daviault Lake and Rectangle Lake have no known surface and sub-surface flow connection to the natural catchments where the Project is planned to be constructed.

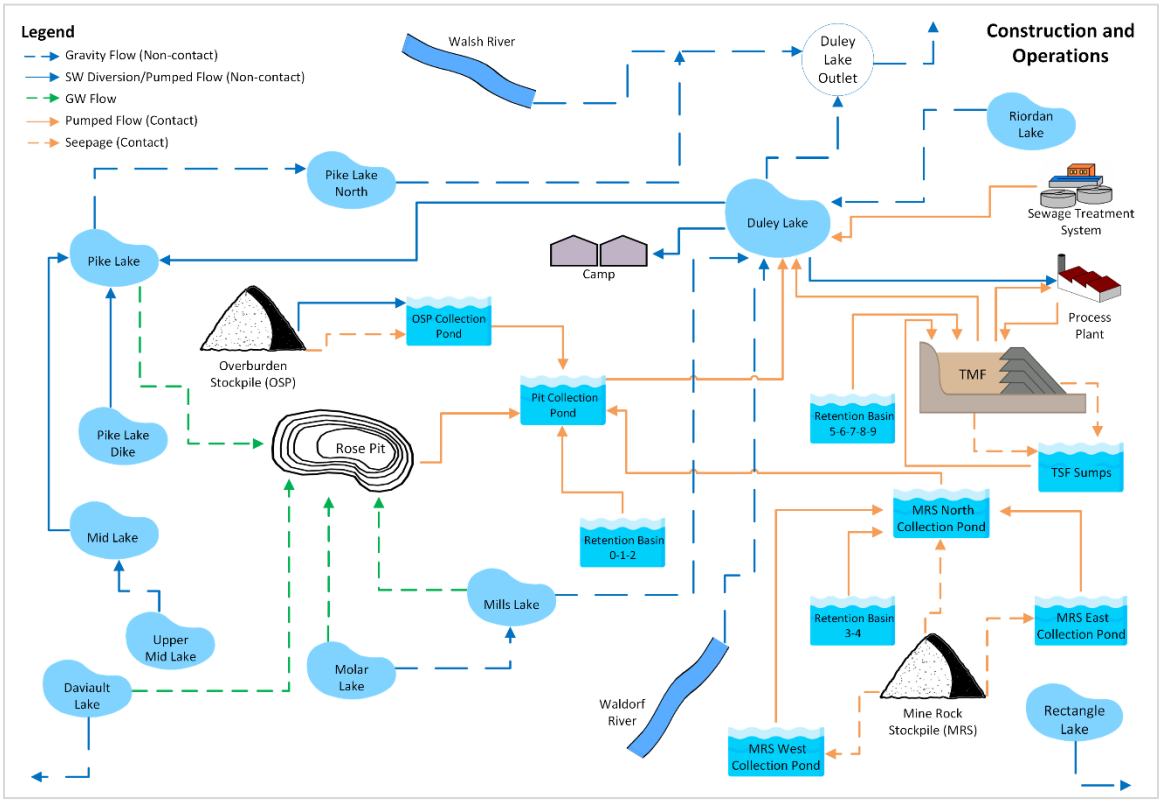
Figure 2-2: Water Balance Model Flow Diagram for Pre-mine Conditions



2.1.2.2 *Construction and Operations*

As the open pit is developed, it is anticipated that it will receive groundwater seepage from nearby lakes (Figure 2-3), with the majority of seepage originating from Pike Lake (AtkinsRéalis, 2024a; Section 2.1.6.1). Mid Lake is diverted to Pike Lake to facilitate the redirection of clean, non-contact water around the pit. Additional water is also transferred from Duley Lake to Pike Lake to mitigate the impact of groundwater seepage from Pike Lake, thereby maintaining lake levels.

Figure 2-3: Water Balance Model Flow Diagram for Construction and Operations Phases



Note: TMF = tailings management facility.

All contact water generated from mine facilities during Construction and Operations phases is planned to be collected and routed through a series of ponds prior to discharge to Duley Lake (Figure 2-3). The Pit collection pond serves as the primary contact water collection pond, receiving dewatering discharge from the Rose Pit sump, pumped flows from the OSP collection pond and retention basin 0-2. The MRS North collection pond collects seepage from the MRS and also reports to the Pit collection pond, which then discharges to Duley Lake.

Seepages from the TMF are collected in sumps and are then pumped back to the TMF pond (Figure 2-3). The process plant uses recycled water from the TMF impoundment and fresh water from Duley Lake, discharging back to the TMF impoundment. The TMF impoundment also receives the pumped discharge from retention basin 5-9. Site discharges from the TMF impoundment are then directed to Duley Lake.

Water retention basins 0 through 9 have been incorporated into the site-wide water balance model. These basins have been designed to manage water from the Project facilities, as provided here (AtkinsRéalis 2025):

- Retention basins 0 through 2 collect water from the low-grade ore stockpile, emergency ore stockpile, emulsion and explosion production plant, and primary ore crusher station. The water from retention basins 0 to 2 is then directed to the Pit collection pond (Figure 2-3).
- Retention basins 3 and 4 manage water from the mine service area and managed within the MRS North collection pond (Figure 2-3).
- Retention basins 5 through 9 collect run-off from the crushed ore stockpile and emergency ore concentrate stockpile. The run-off from these retention basins then reports to TMF impoundment (Figure 2-3).

Run-off from water retention basins is modelled as non-contact run-off and is integrated into overall water management infrastructure. As such, run-off is incorporated into the site-wide water balance and is incorporated into effluent discharges from the Project via the Pit collection pond and TMF.

In addition to water transfers from Duley Lake to Pike Lake and the process plant, Duley Lake also supplies 250 cubic metres per day (m^3/d) of fresh water to the worker accommodations (BBA 2024) (Figure 2-3). Associated treated sewage effluent from the worker accommodations (250 m^3/d; equal to the water supply rate) is then returned to Duley Lake (Figure 2-3).

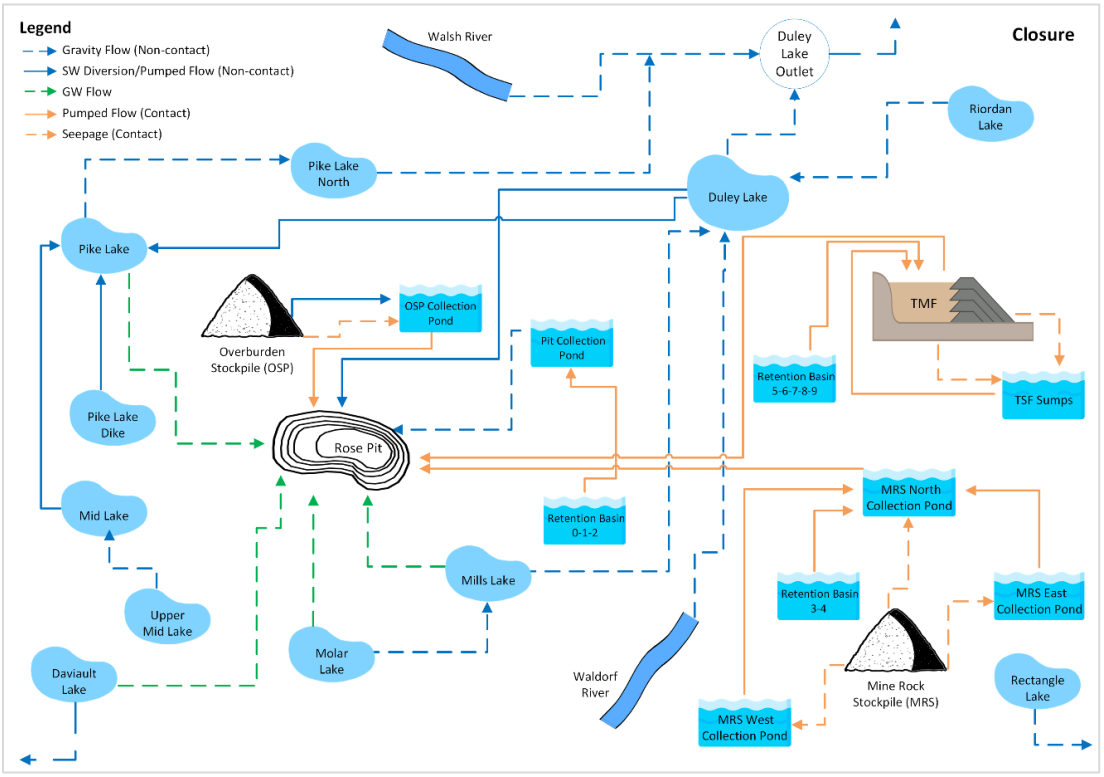
2.1.2.3 Closure

The Closure phase involves the accelerated flooding of the Rose Pit with water transfers from Duley Lake, stockpile collection ponds, and the TMF impoundment (Figure 2-4). During Closure, the operational water management layout is assumed to remain in place, including the water transfers from Duley Lake to Pike Lake (Figure 2-4). During Closure, it is assumed that there is no discharge from mine facilities to the surrounding environment. As the pit fills, the groundwater seepage from the surrounding lakes continues to flow into the pit, though at decreasing rates as the water level in the pit increases (Section 2.1.6.1).

A key component of the pit-filling strategy includes the collection of MRS seepage and OSP run-off, then conveyance of these waters to the bottom of the Rose Pit (Figure 2-5). The pit surface layer, on the other hand, receives run-off from natural catchment areas, freshwater transfers from Duley Lake, and TMF discharge (Figure 2-5). The objectives of this water management strategy are to 1) physically and chemically isolate stockpile seepage within the bottom of the flooded pit; 2) establish permanent stratification (meromixis) in the water column to maintain the isolation of these water types at depth; 3) optimize water quality in the pit lake surface layer to minimize water quality effects on the receiving environment once the surface of the flooded pit begins discharging; and 4) reduce the need for active water treatment during post-closure. Through the Closure

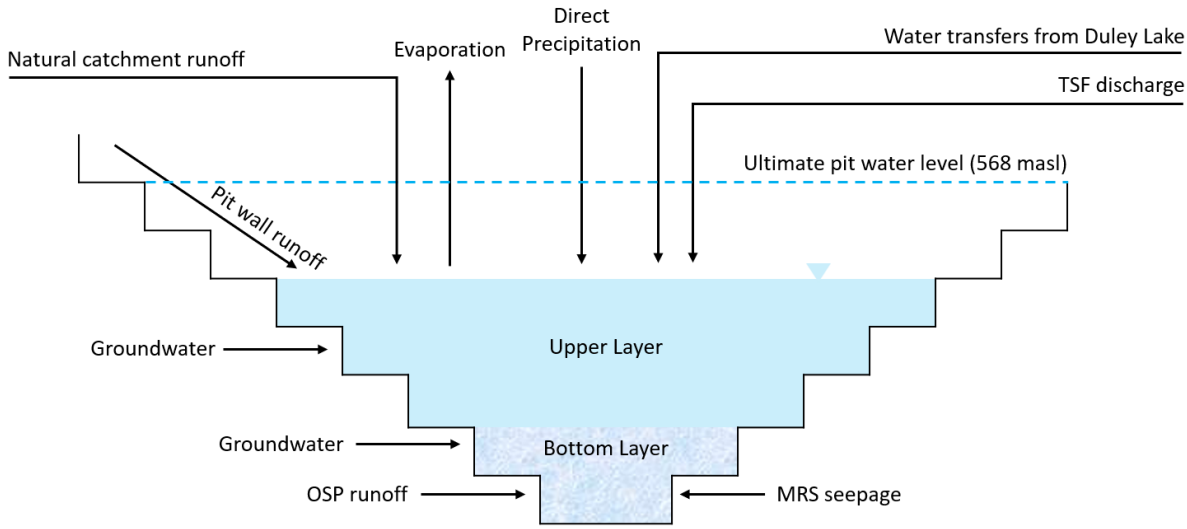
phase, it is assumed that groundwater inflow to the pit is evenly distributed between the bottom and upper pit layers.

Figure 2-4: Water Balance Model Flow Diagram for Closure Phase



Note: TMF = tailings management facility.

Figure 2-5: Conceptual Model Showing the Various Inputs to Rose Pit during Closure

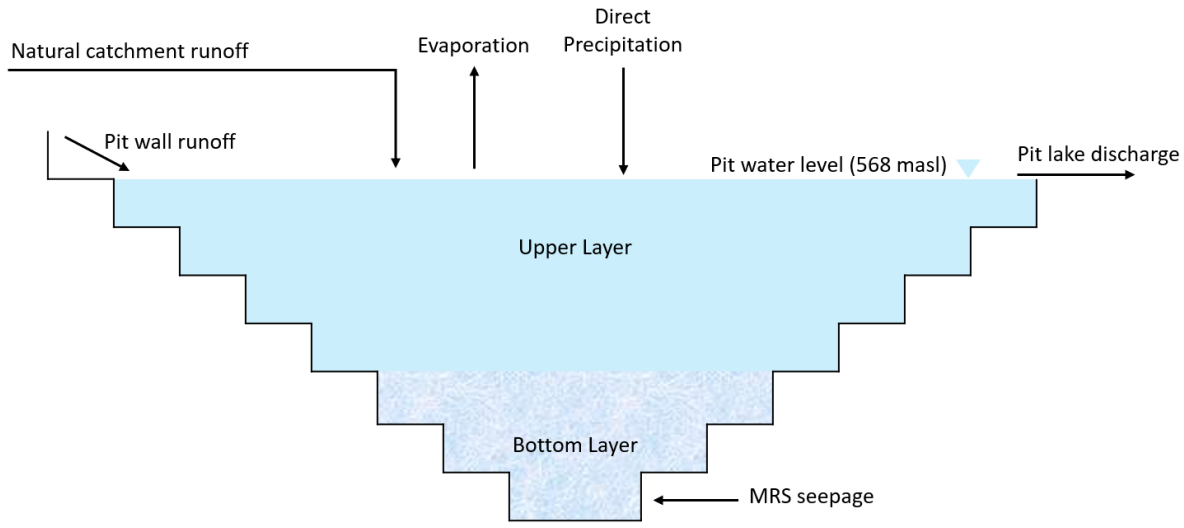


Notes: TSF = tailings management facility; masl = metres above sea level; OSP = overburden stockpile; MRS = mine rock stockpile.

2.1.2.4 Post-closure

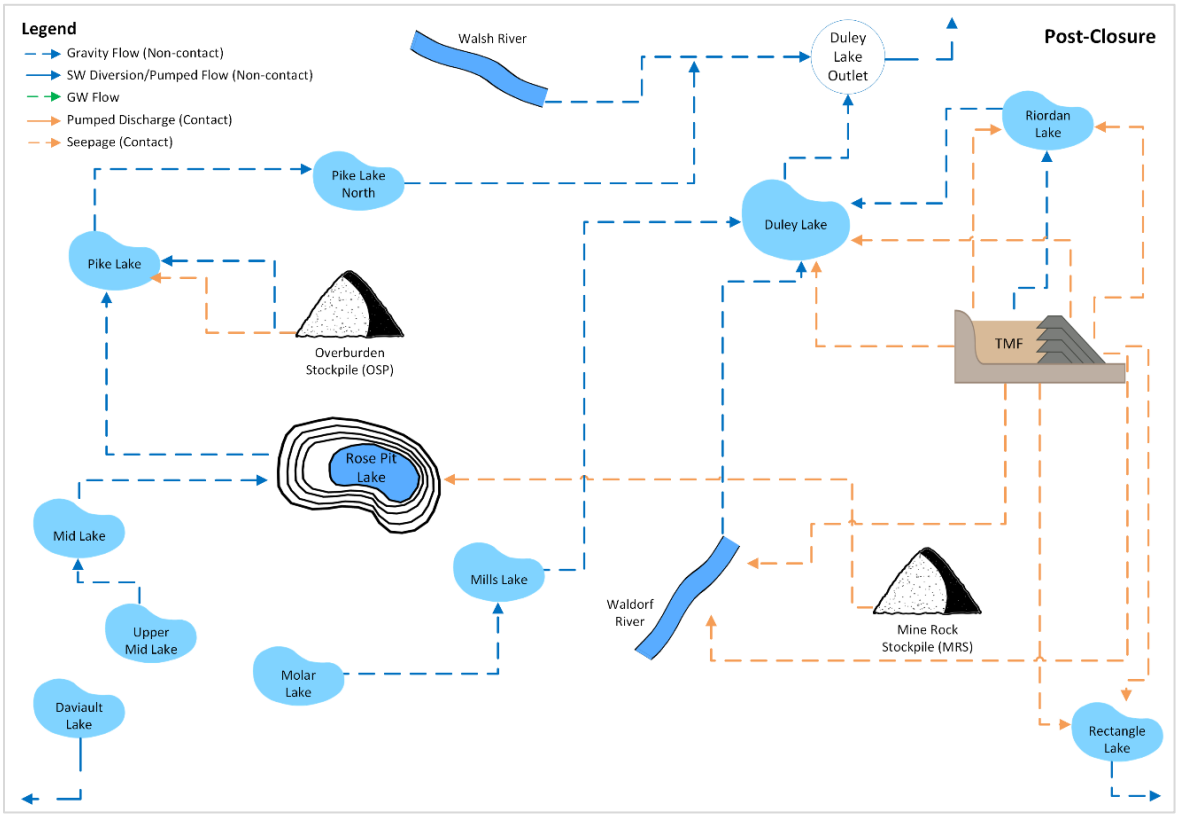
The Post-closure period starts once the pit flooding is complete, and the pit lake discharges into Pike Lake (Figure 2-6 and Table 2-7). It is assumed that the MRS is revegetated, with seepage from the MRS continuing to be pumped into the bottom layer of the pit (Figure 2-6). Surface run-off from the MRS is directed to the surrounding environment, including Duley Lake, Mills Lake, and Waldorf River (Table 2-7). Seepage and surface run-off from the OSP flows into Pike Lake. It is assumed that the TMF is regraded and revegetated, with no ponded water formation allowed on the surface. While surface run-off from the TMF impoundment flows into Riordan Lake, seepage from both the TMF impoundment and dam embankment reports to the surrounding environment, including Duley Lake, Riordan Lake, Waldorf River, and Rectangle Lake.

Figure 2-6: Conceptual Model Showing the Various Inputs to Rose Pit during Post-closure



Notes: masl = metres above sea level; MRS = mine rock stockpile.

Figure 2-7: Water Balance Model Flow Diagram for Post-closure Period

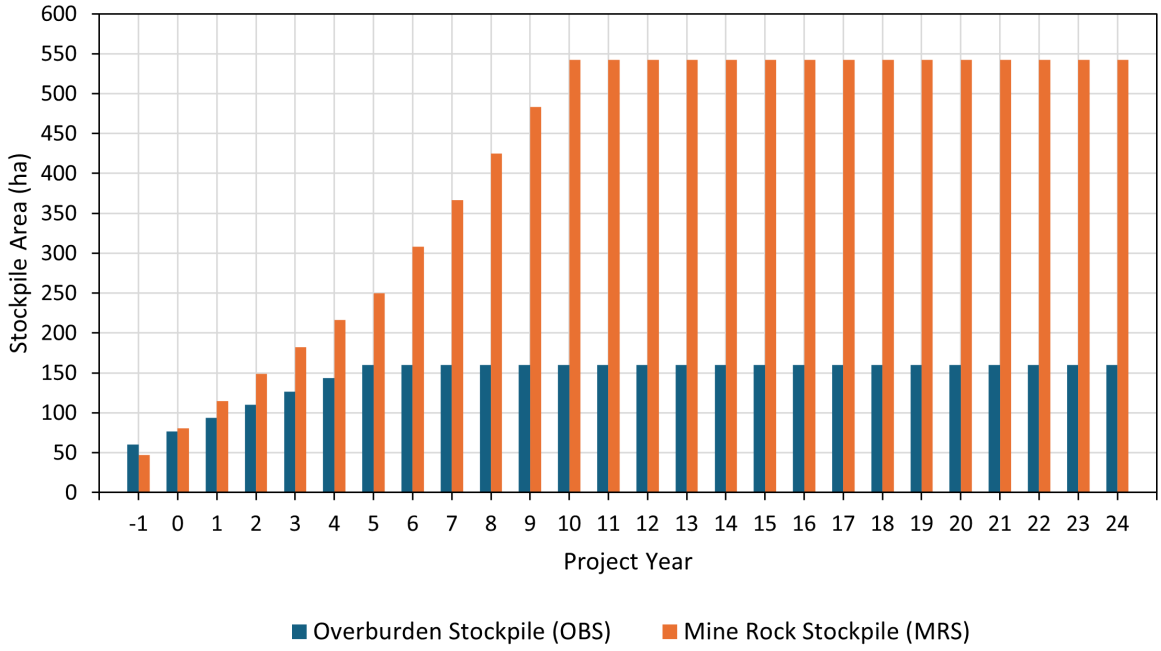


Note: TMF = tailings management facility.

2.1.3 Sub-catchment Delineation

To generate water volume estimates from precipitation inputs, the delineation of both the natural and mine-altered watershed areas was necessary for modelling locations of interest for the Project. Sub-catchment delineations were performed by AtkinsRéalis (AtkinsRéalis, 2025) for mine components from Construction through Operations, including areas for OSP, MRS, and retention basin footprints (Figure 2-8). It is assumed that the entire TMF area of 1,015 ha, including the embankment (96 ha) (WSP, 2024b), will be fully built during the Construction phase.

Figure 2-8: Stockpile Contact Area (hectares) per Project Year



It is assumed that the OSP collection pond is fully constructed and collects run-off from an entire catchment area of 205 ha, including the OSP footprint and natural catchment area, by Year -1. On the other hand, the construction of the MRS collection system occurs alongside the expansion of the MRS footprint, which reaches its ultimate area in Year 10 and remains constant thereafter. By Year 10, the total catchment area for the MRS collection ponds is 680 ha, including the 542 ha of the MRS footprint. The model reflects the annual progression of catchment areas associated with buildout of Project infrastructure.

Champion provided the progress of the open pit surface area throughout Operations (Figure 2-9). It is assumed that the exposed pit wall area will be 47 ha once the pit is flooded to the spillway elevation (568 masl). This means that as the pit floods during Closure, the exposed pit wall area will be reduced from 298 ha at the end of Operations (Year 24; Figure 2-9) to 47 ha by the end of Closure.

Figure 2-9: Pit Wall Area (hectares) per Project Year

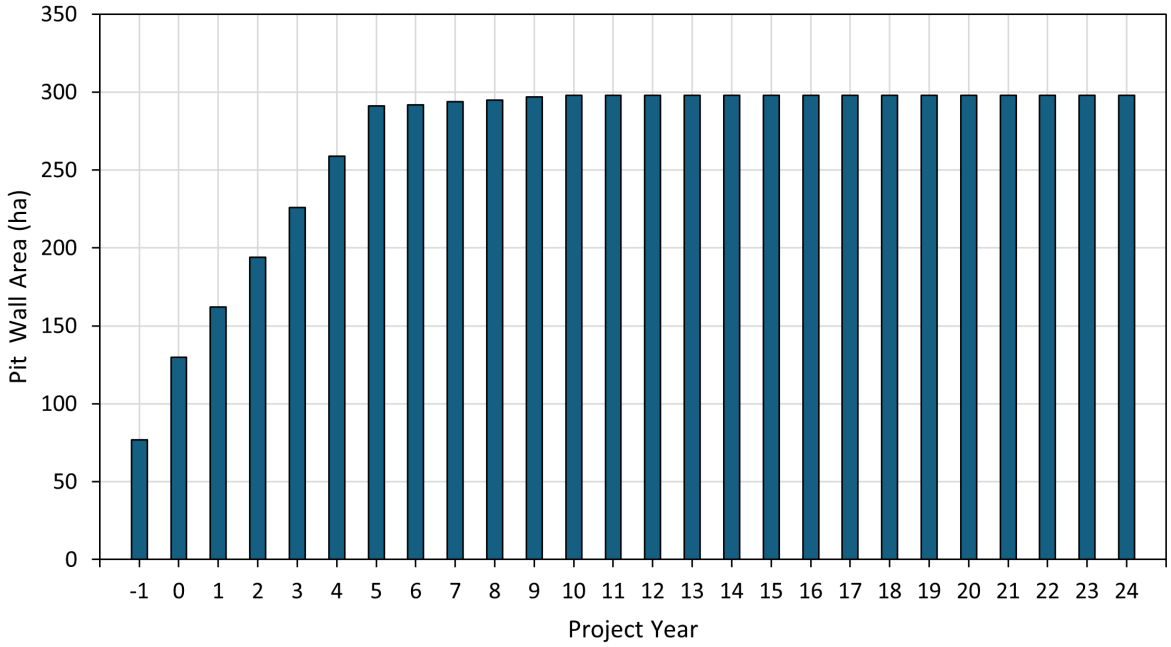


Table 2-2 illustrates the pre-mine catchment areas and the modifications (gains or losses) to these areas resulting from the proposed infrastructure. The modified catchment areas at the end of mine (EOM) reflect the overall impact of the Project, representing the difference between the pre-mine catchment areas and changes caused by the proposed infrastructure when the Project footprint reaches its maximum. The WBWQM represents a total catchment area of 98,917 ha, with the difference composed of the receiving watercourse drainage areas (Table 2-2). It is important to note that Daviault Lake and Rectangle Lake do not have any surface water connection with the Project, nor they do drain to Duley Lake.

Table 2-2: Modifications to Pre-mine Catchment Areas as a Result of Project Infrastructure (end of mine)

Catchment	Pre-mine Catchment Area (ha)	Gains (+) from and loses (-) to other catchments at EOM (ha)										Project Impact at EOM (ha)	Modified Catchment Area at EOM (ha)
		Pike Lake	Rose Lake	Pike Lake Dike	Mid Lake	Rose Pit	Pit Collection Pond	OSP and OSP Collection Pond	MRS and MRS Collection Ponds	TMF	Retention Basins (0 to 9)

2.1.4 Climate and Hydrology Inputs

2.1.4.1 Precipitation

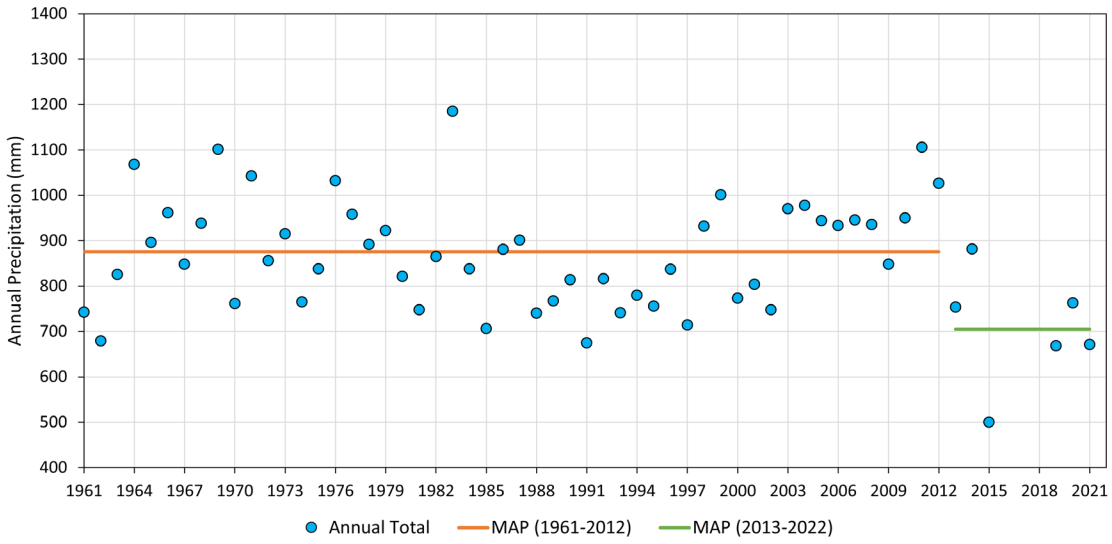
There are three climate stations located within a 50 km radius of the Project site (Table 2-3). The Wabush Lake A station was operated by Environment and Climate Change Canada (ECCC) until 2012, and both active Wabush A stations are currently operated by NAV Canada. The precipitation records from Wabush Lake A station for 1961 to 2012 are mostly complete, but there are substantial data gaps at both Wabush A (1) and Wabush A (2) stations.

Table 2-3: Climate Stations

Station	Station No.	Record Period	Latitude (°)	Longitude (°)	Distance from Project (km)	Elevation (m)
Wabush Lake A	8504175	1961 to 2012	52°55′38″ N	66°52′27″ W	30	551.4
Wabush A (1)	8504176	2013 to 2022	52°55′22″ N	66°51′53″ W	30	551.4
Wabush A (2)	8504177	2014 to 2022	52°55′22″ N	66°51′53″ W	30	551.4

Figure 2-10 illustrates the annual precipitation values between 1961 and 2022, excluding records from Wabush A (1) and A (2) stations when there are more than five days of missing data in any month. Mean annual precipitation (MAP) between 2013 and 2022 is approximately 20% less than the MAP over the 1961 to 2012 period. This difference is mostly due to known issues with the measurement of solid phase precipitation (*i.e.*, gauge undercatch for solid precipitation can reach 20% to 35%, depending on meteorological conditions, the precipitation gauge, and the wind shield used).

Figure 2-10: Annual Precipitation (millimetres) for Wabush Lake A, Wabush A (1), and Wabush A (2) Climate Stations



Note: MAP = mean annual precipitation.

Due to the questionable quality of the more recent records (2013 to 2022) and the extended data gaps at Wabush A (1) and A (2) climate stations, this study inter-compared global and regional climate datasets to provide more reliable precipitation estimates for the Project area. The datasets included the Adjusted and Homogenized Canadian Climate Data (AHCCD), Natural Resources Canada dataset (NRCANmet), ERA5-Land dataset, and Canadian Precipitation Analysis (CaPA) dataset (Table 2-4).

Table 2-4: Regional and Global Precipitation Datasets

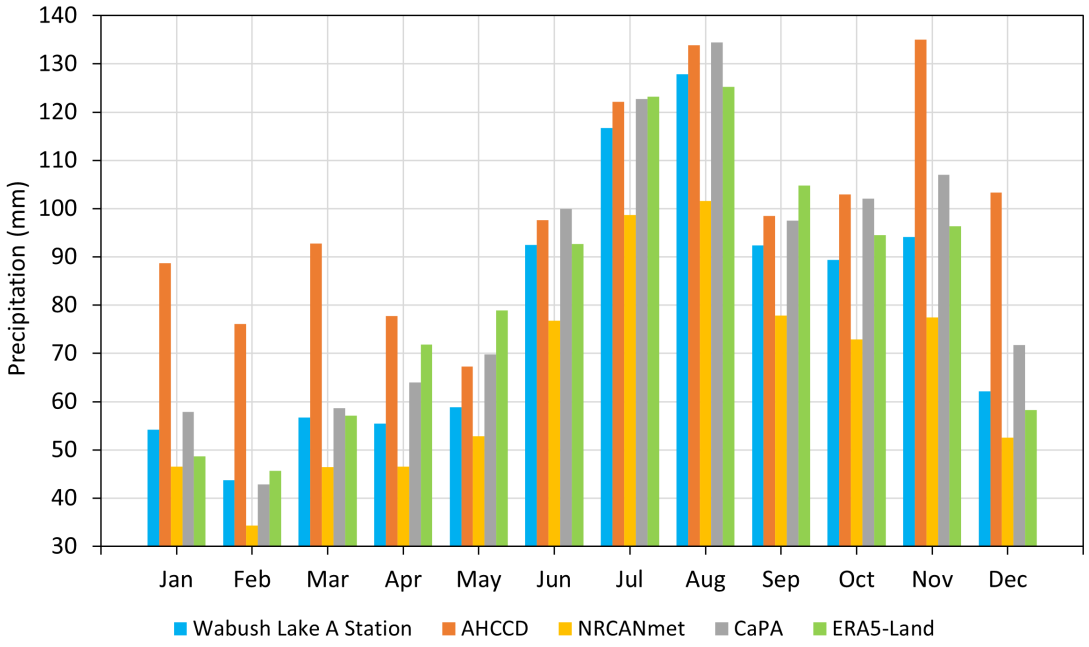
Dataset	Temporal Coverage	Grid Size	Time Step
Adjusted and Homogenized Canadian Climate Data (AHCCD)	1961 to 2012	n/a	Daily
Natural Resources Canada dataset (NRCANmet)	1950 to 2017	~10 km	Daily
Canadian Precipitation Analysis (CaPA)	2002 to 2023	~10 km	6 hourly
ERA5-Land	1950 to 2023	~10 km	Hourly

Note: n/a = not applicable.

The AHCCD dataset provided by ECCC consists of climate station–specific records that incorporate adjustments (derived from statistical procedures) to the original historical station data to account for discontinuities from non-climatic factors, such as instrument changes, station relocation, trace events, and gauge undercatch. In this study, the AHCCD dataset for the Wabush Lake A station has been used. The NRCANmet dataset was produced by interpolating quality-controlled weather station observations by Natural Resources Canada (NRCan) and available at roughly a 10 km^2 grid over Canada. The CaPA dataset is based on a combination of manual and automatic stations maintained by ECCC and observations from the radar network. It is provided at about a 10 km^2 resolution and is used by ECCC for operational purposes. The ERA5-Land dataset produced by the European Centre for Medium-Range Weather Forecasts is a global re-analysis product that provides hourly information of climate variables, including precipitation at roughly 10 km^2 grid spacing. The point data from the closest grid point to the Wabush Lake A station were used for NRCANmet, CaPA, and ERA5-Land datasets.

The AHCCD dataset consistently shows higher values than the station data, with greater discrepancies observed during winter months (Figure 2-11), due to the corrections made to account for wind (gauge) undercatch at the Wabush Lake A station. It is possible that this station underestimated the actual precipitation because of gauge undercatch, as observed at Wabush A (1) and Wabush A (2) stations. The NRCANmet dataset, on the other hand, is consistently biased low relative to the station data by 17% annually (Table 2-5).

Figure 2-11: Monthly Average Precipitation Data for the 2002 to 2012 Period



Notes: AHCCD = Adjusted and Homogenized Canadian Climate Data; NRCANmet = Natural Resources Canada dataset; CaPA = Canadian Precipitation Analysis.

The CaPA and ERA5-Land datasets show comparable values, providing a better estimate of variability and magnitude of monthly station data than the AHCCD and NRCANmet datasets. The station MAP is biased high by less than 10% by ERA5-Land and CaPA datasets over the 2002 to 2012 period (Table 2-5). Out of the assessed datasets, the CaPA precipitation data are recommended to complement the Wabush Lake A station measurements for the 2013 to 2023 period, extending the precipitation record to the present. The CaPA data are considered superior to other gridded products for watershed model applications in Eastern Canada, where the Project site is situated (Gbambie *et al*. 2017).

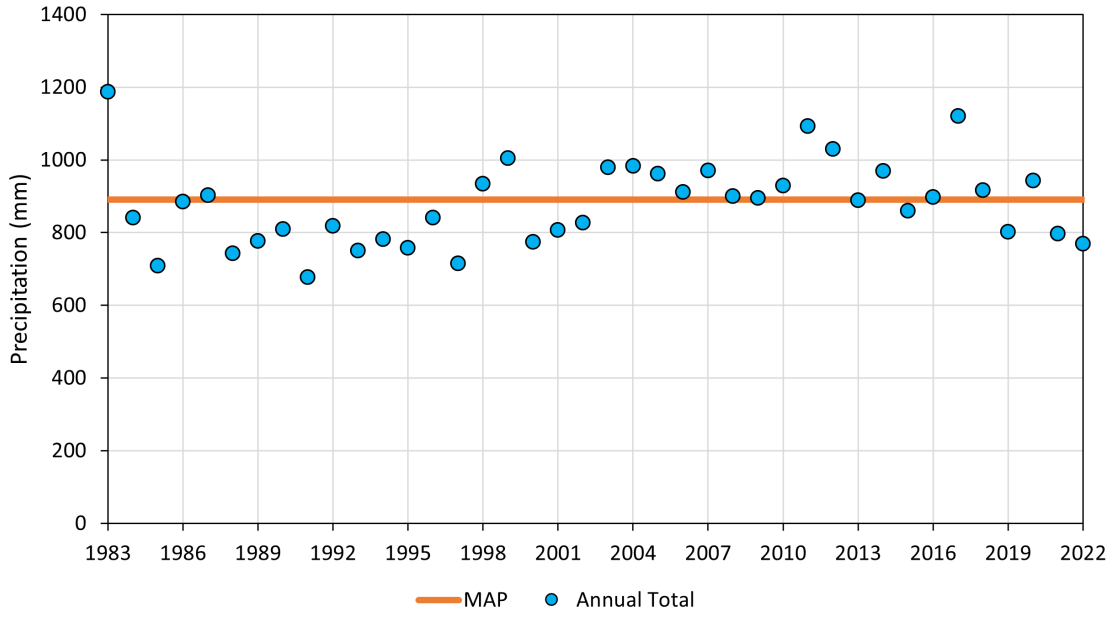
Table 2-5: Mean Annual Precipitation for the 2002 to 2012 Period

Dataset	MAP (2002 to 2013)
Wabush Lake A station	944 mm
AHCCD	1,196 mm
NRCANmet	785 mm
CaPA	1,029 mm
ERA5-Land	990 mm

Notes: AHCCD = Adjusted and Homogenized Canadian Climate Data; NRCANmet = Natural Resources Canada dataset; CaPA = Canadian Precipitation Analysis; MAP = mean annual precipitation.

To create a long-term precipitation time series spanning the last 40 years, the detrended quantile mapping bias correction method, as outlined by Cannon *et al*. (2015), was employed to minimize distributional biases between the CaPA and Wabush Lake A station data. The Wabush Lake Station data, covering the period from 1983 to 2012, were treated as the reference observational dataset, while the CaPA data, which span from 2002 to 2022, were adjusted to match the statistical distribution of the station data. The overlapping period between the two datasets (2002 to 2012) was used to derive correction factors, focusing on aligning the precipitation distributions (*e.g*., quantiles) from both datasets. These correction factors were then applied to the CaPA data to reduce biases and help to keep consistency with the station data. Finally, the adjusted CaPA data were merged with the Wabush Lake A station data to create a continuous, corrected precipitation time series from 1983 to 2022. Based on this blended dataset, MAP ranges from 680 to 1,190 mm over the past 40 years (1983 to 2022), with an average of 890 mm (Figure 2-12).

Figure 2-12: Combined Wabush Lake A and Canadian Precipitation Analysis Annual Precipitation Time Series for the 1983 to 2022 Period

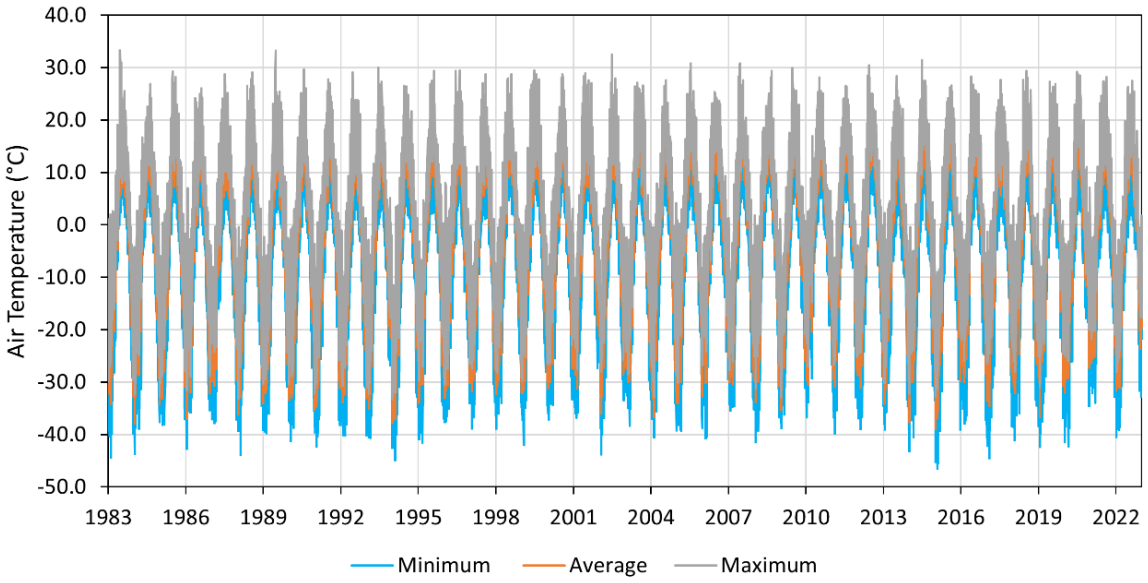


Notes: MAP = mean annual precipitation.

2.1.4.2 Air Temperature

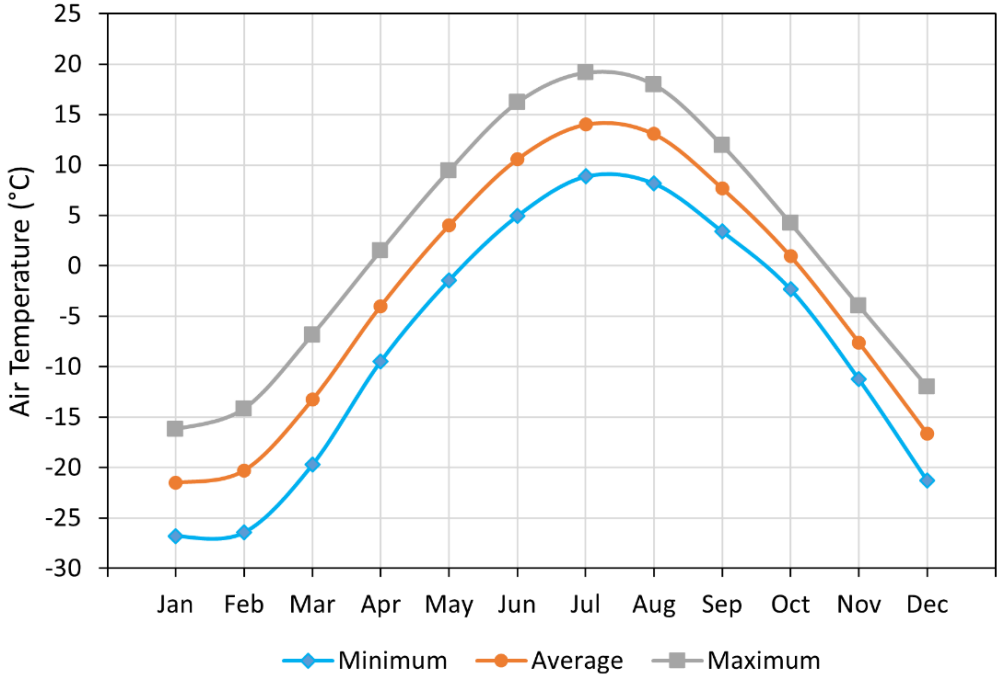
Daily average, minimum, and maximum air temperatures for the Project were derived using the hourly data recorded at the Wabush Lake A, Wabush A (1) and Wabush A (2) climate stations (Figure 2-13). Data gaps were infilled with data from the closest NRCANmet grid point to the Wabush Lake A climate station. Mean annual air temperature at the Project site is -2.7°C for the 1983 to 2022 period.

Figure 2-13: Daily Minimum, Average, and Maximum Air Temperatures for the 1983 to 2022 Period



Mean, maximum and minimum monthly (based on the daily average) temperatures for the Project site over the entire period of record are presented in Figure 2-14. Monthly average temperature ranges from -21°C in January to 14°C in July.

Figure 2-14: Monthly Minimum, Average, and Maximum Air Temperatures (2002 to 2022)



2.1.4.3 Snow Accumulation (snow water equivalent)

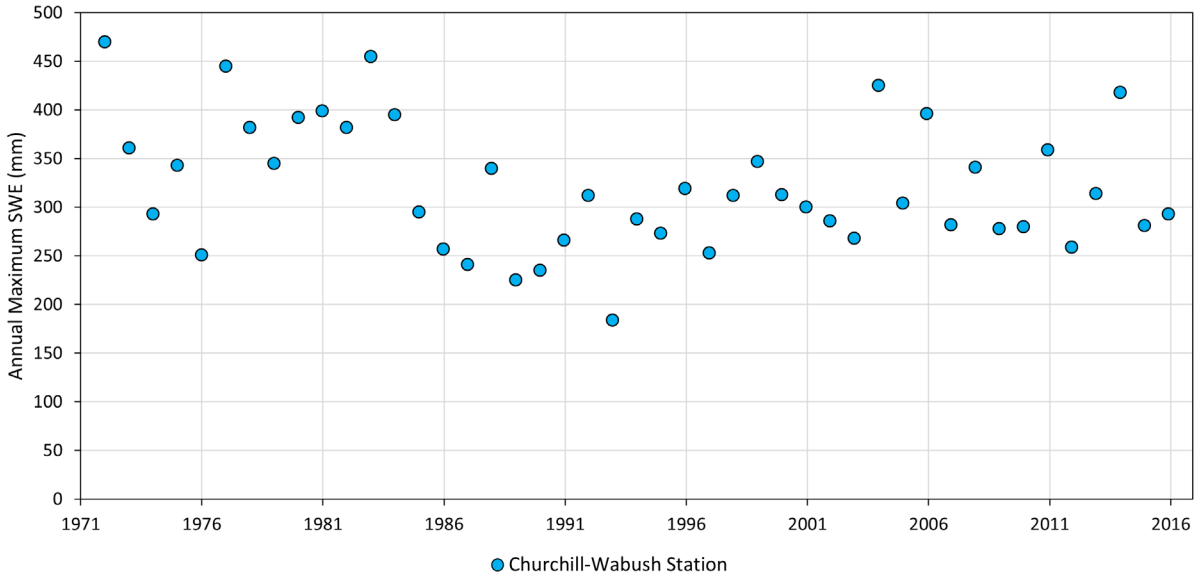
The local streamflow regime is characterized as nival (snowmelt), and thus the annual maximum depth of water contained within the snowpack and available for melt is highly relevant to any water balance modelling exercise conducted in a freshet dominated environment. There is only one snow station in the vicinity of the Project, with long-duration snow water equivalent (SWE) records (Table 2-6). The data for this station were extracted from the Canadian historical SWE dataset—a compilation of manual and automated pan-Canadian observations of SWE collected by national, provincial, and territorial agencies as well as hydropower companies and their partners. The SWE data were used in assessing the performance of the regional watershed model (Section 2.1.5).

Table 2-6: Regional Snow Stations

Station Name	Station Type	Sampling Frequency	Record Period	Latitude	Longitude	Elevation (m)	Distance from the Project (km)
Churchill-Wabush	Manual	Once/twice per month during the snow season	1972 to 2016	52°57′12″ N	66°40′48″ W	551.4	27

The annual maximum SWE measured at Churchill-Wabush station varies from 184 to 470 mm over the period of the record, with an average of 322 mm (Figure 2-15).

Figure 2-15: Annual Maximum Snow Water Equivalent at the Churchill-Wabush Station (1972 to 2016)



2.1.4.4 Iterative Approach to Climate Change

The WBWQM was run with multiple iterations of the input climate data series, to test the effect of multiple climate scenarios on the WBWQM predictions for each year of the mine plan. To accomplish this, the climate series was iterated through the model, by stepping forward one year in the climate record for each iteration. In this way, multiple realizations (n = 40) of the model were run so that each year of the mine life is run with all the possible combinations of the natural climate series. The approach is repeated twice to bring the model period out to calendar year 2100 (Project Year 73). This coincides with the furthest future extent of publicly available climate change projections, and it includes several decades of the Post-closure period.

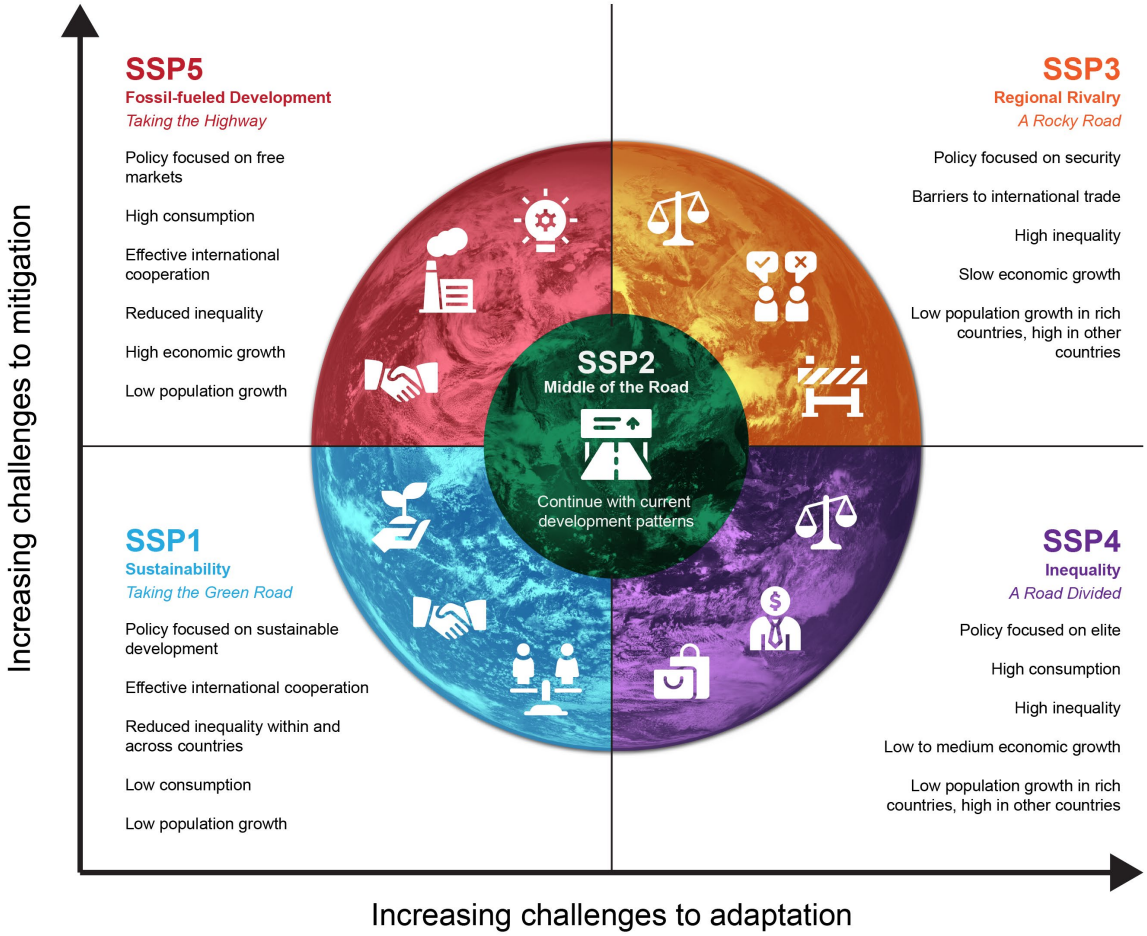
2.1.4.5 Climate Change

Climate change scenario data for the Project site were obtained from downscaled (10 km x 10 km) and bias-adjusted Coupled Model Intercomparison Project Phase 6 simulations, which are featured in the Intergovernmental Panel on Climate Change's Sixth Assessment Report. Coupled Model Intercomparison Project Phase 6 simulations are based on five SSPs, which describe future global development pathways based on different levels of socioeconomic development and challenges to mitigation and adaptation, allowing practitioners to explore climate changes across a range of very different futures (Figure 2-16).

The datasets were accessed via the Power Analytics and Visualization for Climate Science platform (https://pavics.ouranos.ca) and included daily estimates from 40 models for air temperature (minimum and maximum) and precipitation, driven by SSP2-4.5, a middle-of-the road scenario (Figure 2-16), which represents an intermediate greenhouse gas emission scenario.

Compared to the historical climate (defined here as 1983 to 2022), mean annual temperature at the Project site is expected to increase across all future periods under the SSP2-4.5 scenario (Table 2-7). By the 2060 to 2080 period, the SSP2-4.5 scenario suggests that mean annual temperature will surpass the freezing point, marking a shift in climatic conditions. Precipitation is projected to increase by 11% between 2040 and 2060 and by 18% between 2080 and 2100, relative to the historical climate. However, snowfall as a proportion of total precipitation is likely to decrease in the future, reflecting the effect of rising temperatures.

Figure 2-16: The Five Shared Socioeconomic Pathways and the Associated Challenges to Mitigation and Adaptation



Source: ClimateData.ca.

Table 2-7: Mean Annual Temperature, Precipitation and Snowfall-Rainfall Partitioning in Precipitation for the Historical and Future Periods Under SSP2-4.5 Scenario

Climate Variable (annual mean)	Historical	Future (SSP2-4.5)		
	1983 to 2022	2040 to 2060	2060 to 2080	2080 to 2100
Air temperature (°C)	-2.7	-0.3	0.4	1.2
Precipitation (mm)	880	980	1010	1040
Rainfall (mm)	505	634	673	712
Snowfall (mm)	375	346	338	328

2.1.4.6 Regional Surface Hydrology

There are two Water Survey of Canada stations located near the Project site with long-term streamflow records (Table 2-8) within the Wabush Lake at Lake outlet basin. Among these stations, the Flora Creek gauge (03OA015) is the only one that is representative of unregulated (natural) streamflow conditions in the region; therefore, this record was used in calibrating and validating the regional watershed model (Section 2.1.5).

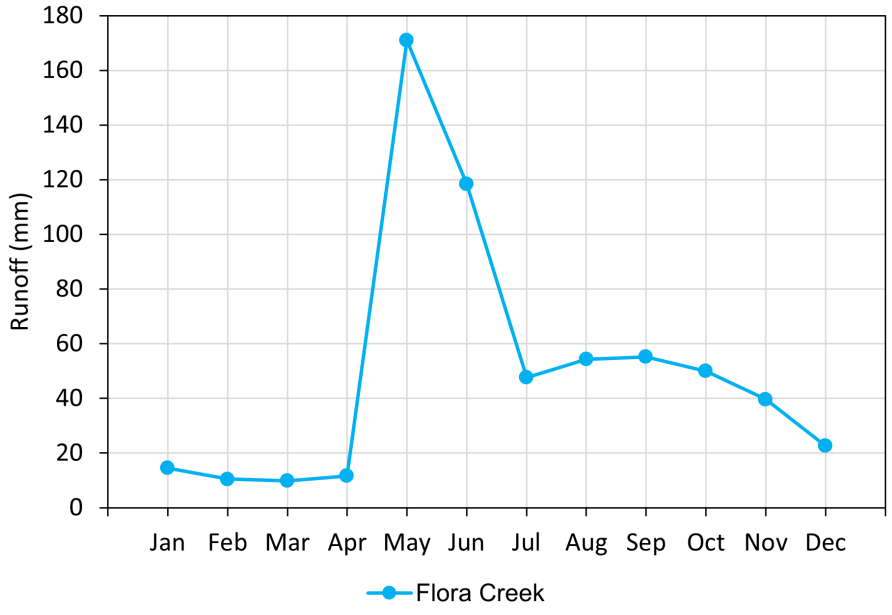
Table 2-8: Regional Hydrometric Stations

Station Name	Station Number	Years	Latitude	Longitude	Drainage Area (km^2)
Luce Brook below Tinto Pond	03OA012	2007 to 2023	52°59′15″ N	66°52′37″ W	43
Flora Creek below Trans Labrador Highway	03OA015	2012 to 2023	52°57′48″ N	66°50′12″ W	140
Wabush Lake at Lake Outlet	03OA005	2007 to 2023	53°09′06″ N	66°47′07″ W	1,600

Notes: km^2 = square kilometre.

The drainage area of Flora Creek is 140 km^2, 60% of which is covered by coniferous forests. Shrubs and lakes/wetlands are other important landscape units, occupying 23% and 14% of the basin, respectively. The rest of the basin (3%) is composed of barren lands and urban areas. The elevation in the basin ranges from 537 to 723 masl, with slopes ranging from 0° to 14°. The streamflow regime is characterized as nival with approximately half of the mean annual run-off reporting in the months of May and June because of snowmelt (Figure 2-17). Streamflow declines until the annual minimum is reached in March, prior to the onset of freshet (Figure 2-17).

Figure 2-17: Average Monthly Run-off (mm) for the Flora Creek Discharge Gauge



2.1.5 Watershed Model

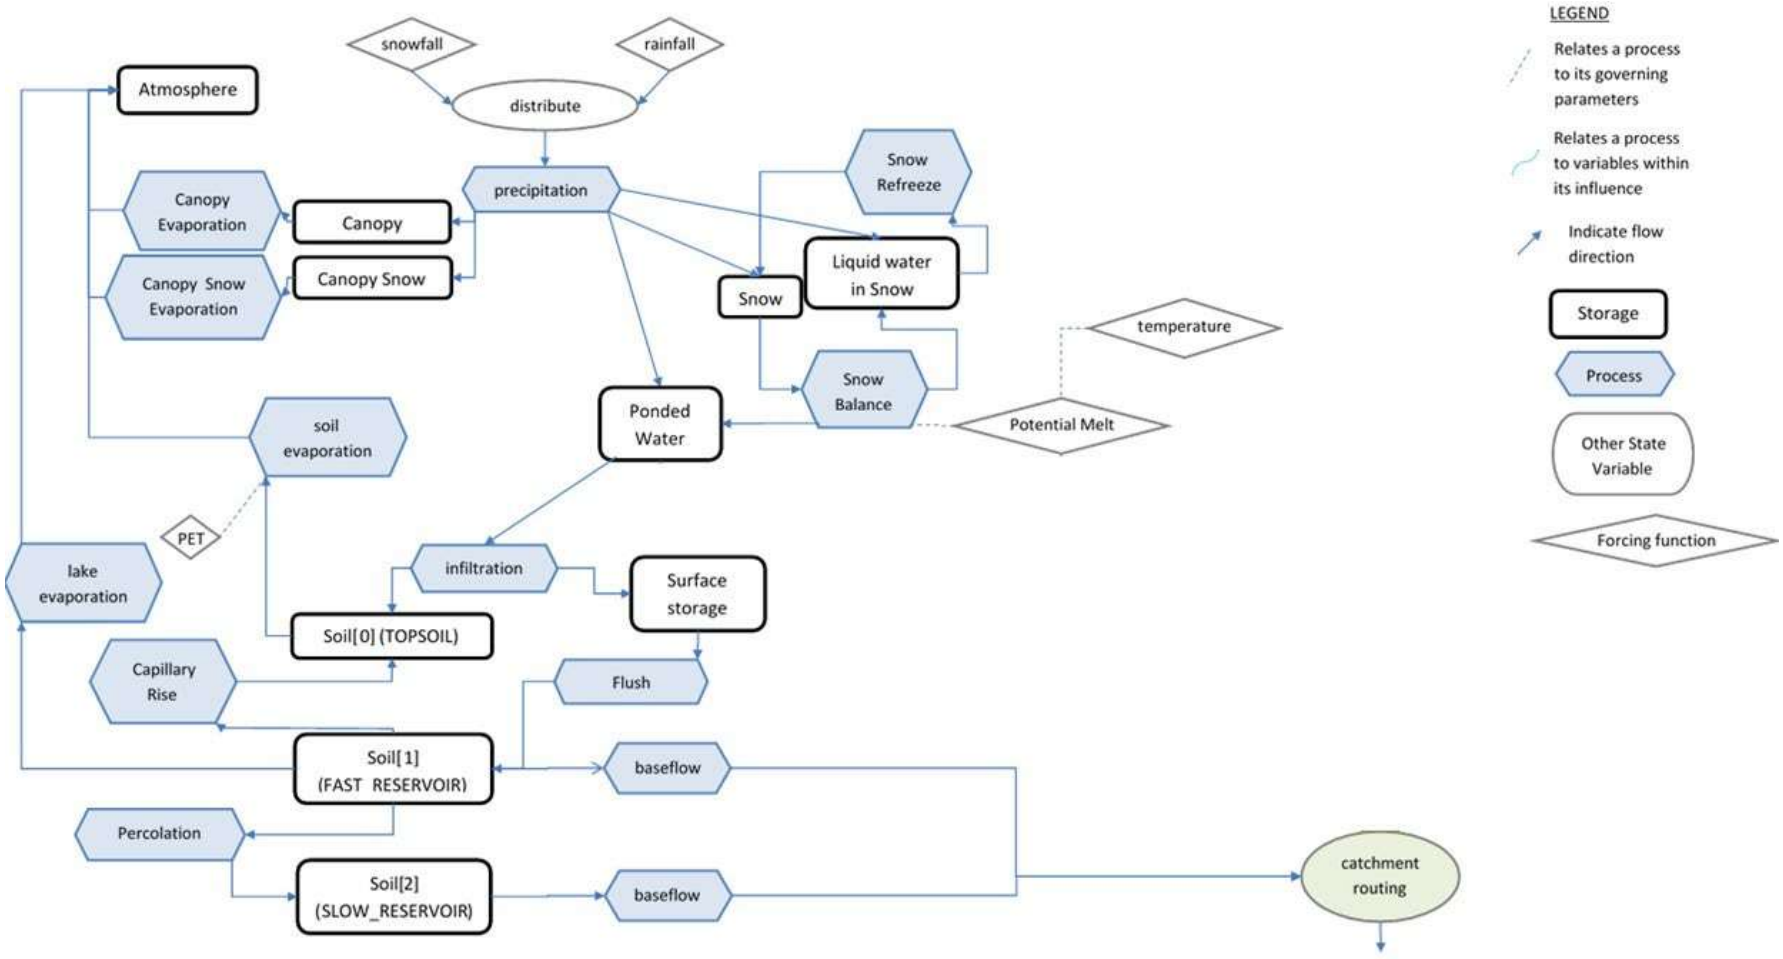
A watershed model was constructed to represent natural (non-contact) catchment flows as a function of climate. The outputs from this watershed model, including the rainfall component of precipitation, snowmelt, (natural) catchment run-off, and evaporation, were used as inputs to the site-wide WBM.

The hydrological model employed to simulate the Flora Creek basin is Environment Canada version of HBV (Hydrologiska Byråns Vattenavdelning) hydrological model (HBV-EC) (Bergström 1992) emulated with the Raven Hydrological Modelling Framework, version 3.6 (Craig *et al*. 2020). The Raven HBV-EC model is a semi-distributed hydrological model that is based on hydrological response units (HRUs), each defined by a distinct combination of physical attributes such as land use, vegetation cover, terrain type, soil profile, and bedrock geology. The model follows a water balance approach to each HRU in the model domain, helping to ensure the conservation of mass.

The model requires daily precipitation, as well as air temperature (minimum, average, and maximum) to simulate basin hydrology. Its algorithms integrate both conceptual and physically based parameterizations. The model consists of three components: (i) a snow routine for snow accumulation and snowmelt based on the degree-day method; (ii) a soil routine that controls the proportion of rainwater and snowmelt, which generates excess water after considering soil moisture and evaporation requirements; and (iii) a run-off generation routine consisting of an upper, non-linear reservoir that represents fast discharge and a lower linear reservoir that represents slow discharge or baseflow (Figure 2-18).

HRUs were defined in the Flora Creek basin by finding the unique spatial overlay of land cover type, elevation bands, aspect, and slope. Land cover data included 30 m spatial resolution 2020 Land Cover Map of Canada, generated by the Canada Centre for Remote Sensing. Elevation bands, slope, and aspect values were derived from the Canadian Digital Elevation Model at 20 m spatial resolution provided by Natural Resources Canada. This overlay generated a total of eight HRUs over the Flora Creek basin.

Figure 2-18: The Schematic of Raven HBV-EC

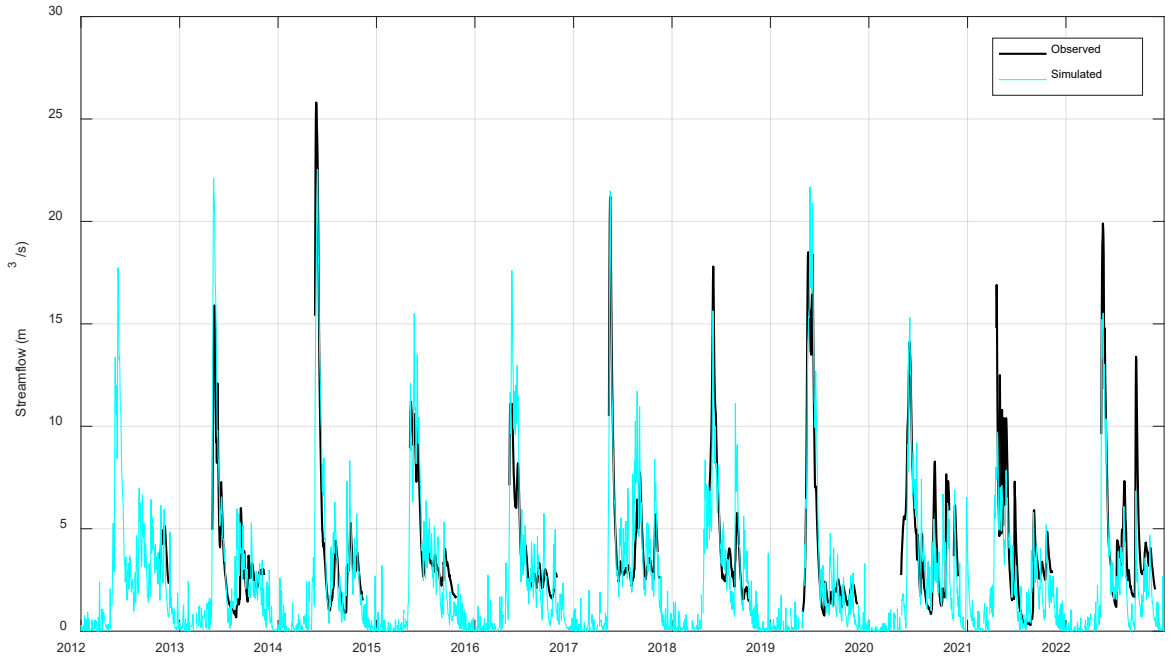


The combined daily precipitation time series from Wabush Lake A and CaPA (Section 2.1.4.1), and daily minimum, average, and maximum air temperatures from Wabush Lake A (Station 2.1.4.2), were used to drive the HBV-EC watershed model.

Model calibration was conducted by adjusting key parameters related to evapotranspiration, soil properties, snow dynamics, and routing. The performance of the calibrated model in simulating streamflow was assessed using the Kling-Gupta Efficiency (KGE) metric, optimized through the Dynamically Dimensioned Search algorithm (Tolson and Shoemaker 2007), a global optimization method with a budget of 1,000 iterations. The KGE was selected as the primary evaluation metric due to its ability to overcome the limitations of traditional measures such as the Nash-Sutcliffe Efficiency and R-squared metrics, which primarily focus on reproducing the mean and variance of observed data. The KGE ranges from negative infinity to 1, with a value of 1 indicating perfect agreement between model simulations and observed data.

Simulated streamflow was compared at the outlet of the catchment for the calibration (2012 to 2018) and validation (2019 to 2022) periods (Figure 2-19). The KGE statistic was above 0.8 for both calibration and validation periods, which suggests that the model is sufficiently reliable in generating representative hydrographs for the Flora Creek basin.

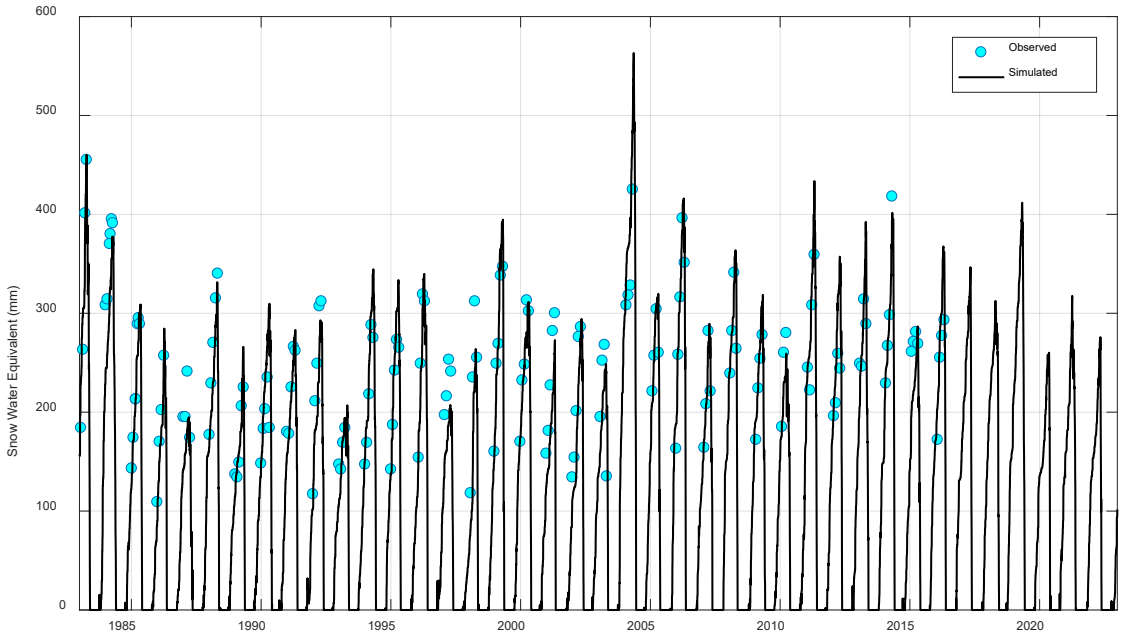
Figure 2-19: Time Series of Observed and Modelled Flora Creek Streamflow



Note: m^3/s = cubic metres per second.

Good agreement between simulated and observed snow water equivalent (Figure 2-20) demonstrates that the model performs sufficiently well in capturing snow accumulation and ablation magnitude and timing. This is highly encouraging given that snowmelt run-off largely dominates the streamflow in the region. Taken together, the model developed for the Flora Creek basin adequately simulates the unimpacted natural streamflow conditions in the region and the watershed model outputs, including the rainfall component of precipitation, snowmelt, evapotranspiration (ET), and streamflow, which can be used to drive the site-wide WBM.

Figure 2-20: Comparison of Simulated and Observed Snow Water Equivalent



2.1.6 Mine Component Water Balance Inputs and Assumptions

The mine water balance modelling approach differs depending on the mine component in each question. Key model inputs and assumptions for mine component water balances are based on studies and supporting water management plans developed for the Project, as summarized here:

2.1.6.1 Pit and Water Management Structure

- Storage capacity (volume-elevation-area) curves for pit and associated water management infrastructure, including the Pit collection pond, Pike Lake, and Mid Lake diversions, were provided by AtkinsRéalis (2024a).

- Total rainfall plus snowmelt on open pit walls and floors is assigned to a run-off coefficient of 0.59 (AtkinsRéalis, 2024a), based on the annual pit wall area (Figure 2-9).
- Pump and treatment rates for water management infrastructure, including the pit sump, Pit collection pond, OSP collection pond, MRS collection ponds (east, west and north), Pike Lake dike, and Mid Lake are determined by AtkinsRéalis (2024a and 2025) consistent with the Project (Table 2-9).Total groundwater (GW) inflow estimates to the pit per Project year were provided by AtkinsRéalis (2024b) (Table 2-10).
- Total GW rates at Closure were calculated as a function of water elevation in the flooded pit (Table 2-11), based on the relationhip between GW inflow and head provided by AtkinsRéalis (2024b).
- The proportion of Pit GW inflow sources by lake from Construction though Closure are assumed to be consistent with the proportion provided for EOM (2024b) (Table 2-12).

Table 2-9: Pump Rates for Water Management Infrastructure

Water Management Structure	Pump Capacity (m^3/hr)
Rose Pit sump	4,680
Pit collection pond	7,100
Pike Lake dike	495
Mid Lake	1,900
OSP collection pond	1,480
MRS East collection pond	2,970
MRS West collection pond	1,944
MRS North collection pond	6,030

Notes: m^3/hr = cubic metres per hour; OSP = overburden stockpile; MRS = mine rock stockpile.

Table 2-10: Groundwater Inflows to Rose Pit during Construction and Operations

Project Year	Groundwater Inflow to Pit (m^3/d)
-1	3,988
0	9,735
1	12,365
2	15,096
3	16,261
4	17,607
5	19,803
6	22,286
7	23,478
8	25,292
9	26,573
10	28,023
11	28,939
12	29,455
13	30,179
14	31,587
15	33,038
16	34,039
17	35,352
18	36,269
19	37,081
20	38,415
21	39,280
22	39,604
23	40,126
24	40,430

Notes: m^3/d = cubic metres per day.

Table 2-11: Groundwater Inflows to Rose Pit in Closure

Water Elevation in Flooded Rose Pit (m)	Groundwater Inflow to Pit (m^3/d)
67	40,430
100	29,834
200	12,133
300	4,933
400	2,006
500	815
520	0
568	0

Note: m^3/d = cubic metres per day.

Table 2-12: Pit Groundwater Inflow Contribution by Lake

Lake	Groundwater Inflow Contribution (%)
Pike Lake	72.1%
Lac Daviault	17.2%
Mills Lake	1.3%
Molar Lake	0.3%
Other lakes	9.1%

2.1.6.2 Stockpiles

Precipitation that falls onto a stockpile can follow several pathways: it may infiltrate into the stockpile, run off the surface, or evaporate from the stockpile area. Infiltration typically results in basal seepage at the base of the pile. The distribution of these fluxes is influenced by revegetation. The following assumptions have been made regarding the basal seepage and surface run-off calculations for the stockpiles:

- The OSP is assumed to be covered with vegetation throughout Operations, Closure, and Post-closure, while the MRS remains without vegetation until the Post-closure period (Okane 2024a).
- For the OSP, annual average effective precipitation during Operations through Post-closure is distributed as follows: 20% surface run-off, 40% infiltration, and 40% evapotranspiration (Okane, 2024c).
- During Operations and Closure, annual average basal seepage from the MRS is estimated with 70% of rainfall and snowmelt, with the remaining 30% contributing to evapotranspiration (Okane, 2024c). The WBM assumes that no surface run-off

is generated from the MRS during Operations and Closure. This is conservative, in that the final volume of water reporting from the MRS is assumed to have infiltrated the pile and has therefore incorporated the full parameters of potential concern (POPCs) loads from the MRS rather than a non-contact or hybrid geochemical signature.

- In the Post-closure period, once the MRS is vegetated, it is assumed to follow a similar flux distribution to the OSP, with 20% surface run-off, 40% infiltration, and 40% evapotranspiration.
- Basal seepage and surface run-off from the OSP are collected with the OSP collection pond during Operations, while the basal seepage from the MRS is collected with a series of MRS collection ponds (east, west, and north).

Stockpiles are expected to attenuate streamflow locally, as the high pore space volume and higher than natural proportion of fines act to slow run-off generation as meteoric water works its way through the stockpiles. To account for this attenuation, the seepage from both stockpiles is calculated based on the annual averages of infiltration from the previous water year.

2.1.6.3 Tailings Management Facility

- Flow terms associated with the ore and tailings production include discharge from mill to the tailings thickener, discharge from thickener to the TMF, overflow from the thickener, water retained in the consolidated tailings mass, moisture going into the mill with the ore, moisture leaving the mill in the concentrate, clean make-up water required in the mill (Duley Lake), water lost in the mill to evapoaration and spillage, and other make-up water required in the mill (TMF pond) and were obtained from the TMF water balance model developed for the PFS (WSP 2024b).
- Surface flow terms for the TMF, including run-off from natural ground, prepared ground, and dry tailings, are calculated using associated run-off coefficients and draingae areas (WSP 2024b) applied to the daily total rainfall plus snowmelt.
- The seepage emanating from the TMF impoundment is dervied from toe seepage modelling (WSP 2024b).
- Since the TMF dam embankment is planned to be contructed using mine rock, it is assumed it will follow a water flux distribution similar to the MRS, where 70% of the rainfall and snowmelt iniltrates and becomes basal seepage, while the remaining 30% is lost to the evapotranspiration. The WBM assumes no surface run-off from the TMF embankment. This flux distribution is applied from Operations through Post-closure, as the TMF embankment dam is expected to remain uncovered (Okane 2024a).

2.1.6.4 Other Water Management Infrastructure

- The potable water supply for the worker accommodations and operation is sourced from Duley Lake (same intake as fresh water source for the mill) at a rate of 250 m^3/d (1,000 total workers at 250 L/worker/d) consistent with the waste and wastewater treatment design (BBA 2024). This is a conservative assumption applied to all phases of the model, as it is planned that 600 workers will be employed during Operations.
- Sewage effluent from the Project is managed in a tertiary biological treatment plant (BBA 2024). Effluent discharge rates are consistent with potable water supply intake rates (250 m^3/d). Effluent from advanced (tertiary) treatment is suitable for direct discharge to the environment and is assumed to discharge directly to Duley Lake. Nitrate and ammonia concentrations in effluent from the sewage treatment plant are assumed to be 1 mg/L and 37.5 mg/L (as N), respectively (BBA 2024).

2.1.6.5 Mine Water Intake and Effluent Discharge Infrastructure

- Fresh water supply for the process plant is sourced from Duley Lake via a pipeline adjacent to process plant, consistent with the Kami Project 2012 EIS (Alderon 2012) and the TMF water balance (WSP 2024b). Water transfers to Pike Lake during Operations and Closure, and to the Rose Pit during Closure, are assumed to occur via the same intake structure.
- Project effluent is discharged as a single outfall to Duley Lake via a pipeline and diffusor, consistent with the 2012 EIS (Alderon 2012). Surge storage of effluent is managed via the Pit collection pond and the TMF pond.
- Water treatment for the removal of total suspended solids (TSS) will be applied as required to meet effluent discharge standards (Section 2.2.1). Mitigation of TSS will be achieved through implementation and management of sedimentation and erosion control, consistent with source control best practices. Supplemental TSS mitigation will be provided by the Pit collection pond and TMF pond. An active water treatment plant located within the mill complex provides TSS removal via conventional sedimentation processes and as required to manage red water associated with mill process water and TMF discharge.

2.1.7 Water Balance Model Outputs

Water balance model outputs are produced for all phases of the Project, including Construction (Year -1), Operations (Year 0 through Year 24), Closure (Year 25 through Year 36), and Post-closure (Year 37 through Year 73). Three selected flow scenarios are

simulated based on annual precipitation (Figure 2-12). The selected model scenarios are as follows:

1) MAP, representing one of the climate year closest to the MAP value of 890 mm (2016)
2) 25th percentile (P25), corresponding to the climate year closest to the 25th percentile of the precipitation record at 780 mm (1994)
3) 75th percentile (P75), representing the climate year closest to the 75th percentile of the precipitation record at 960 mm (2014)

These are the water balance model outputs by phase and period:

- Rose Pit (Operations, Closure, and Post-closure)
- Pit collection pond (Operations)
- Duley Lake (Operations and Closure)
- Pike Lake (Operations and Closure)

2.2 Water Quality

Water quality model boundaries, background inputs for undisturbed non-contact areas, and geochemical source terms for mine disturbance areas (contact areas) are presented here.

2.2.1 Water Quality Guidelines

Applicable water quality regulations and standards that apply to the Project include the following:

- *Metal and Diamond Mining Effluent Regulations* (MDMER), which apply to controlled discharges (exclusive to Duley Lake) from the Project during Operations.
- Estimates of site discharge water quality are compared to maximum authorized monthly mean concentrations for prescribed deleterious substances (MDMER Schedule 4; Table 2-13).
- Ambient surface water quality guidelines for the projection of aquatic life established by the Canadian Council of Ministers of the Environment (CCME) and Federal Water Quality Guidelines (FWQG) (Table 2-14) for the protection of drinking water. These water quality guidelines apply to the receiving environment and are used to identify POPCs for further assessment. Water quality guidelines do not apply to controlled discharges from the Project.

Modelled parameters include the full suite of anions and cations consistent with the parameters listed in Table 2-13 and Table 2-14 with the exception of radium and total suspended solids.

Table 2-13: *Metal and Diamond Mining Effluent Regulations* Discharge Limits

Parameter	Maximum Authorized Monthly Mean Concentration
Total arsenic	0.10 mg/L
Total copper	0.10 mg/L
Total cyanide	0.50 mg/L
Total lead	0.08 mg/L
Total nickel	0.25 mg/L
Total zinc	0.40 mg/L
Total suspended solids	15.00 mg/L
Total radium 226	0.37 Bq/L
Un-ionized ammonia nitrogen (as N)	0.50 mg/L

Notes: MDMER = *Metal and Diamond Mining Effluent Regulations*; mg/L = milligrams per litre; Bq/L = becquerels per litre.

Table 2-14: Canadian Council of Ministers of the Environment and Federal Water Quality Guidelines

Parameters	Unit	CCME[1] and FWQG[2] Guideline	
General Parameters		**Short Term**	**Long Term**
Alkalinity	mg/L as $CaCO_3$	-	-
Acidity	mg/L as $CaCO_3$	-	-
TDS	mg/L	-	-
Anions & Nutrients		**Short Term**	**Long Term**
Fluoride	mg/L	-	0.12
Chloride	mg/L	640	120
Sulphate	mg/L	-	-
Nitrite	mg/L as N	-	0.06
Nitrate	mg/L as N	124	2.9
Phosphorous	mg/L	-	Guidance Framework
Ammonia (total)	mg/L as N	-	variable (temp, pH), 1.54
Metals		**Short Term**	**Long Term**
Silver	µg/L	-	0.25[T]
Aluminum	µg/L	-	variable (DOC, hardness, pH), 557[(T)]
Arsenic	µg/L	-	5[T]
Boron	µg/L	29,000[T]	1,500[T]
Barium	µg/L	-	-
Beryllium	µg/L	-	-
Bismuth	µg/L	-	-
Calcium	µg/L	-	-
Cadmium	µg/L	variable (hardness), 0.76[(T)]	variable, 0.07[(T)]
Cobalt	µg/L	-	variable (hardness), 0.67[(T)]
Chromium	µg/L	-	5[(T)]
Copper	µg/L	-	variable (temp, pH, DOC, hardness), 2.6[(D)]; variable (hardness), 2[(T)]
Iron	µg/L	-	variable (DOC, pH), 2,230[(T)]
Mercury	µg/L	-	0.026[T]
Potassium	µg/L	-	-
Lithium	µg/L	-	-
Magnesium	µg/L	-	-
Manganese	µg/L	variable (hardness), 2,770[(D)]	variable (hardness), 350[(D)]
Molybdenum	µg/L	-	73[T]
Sodium	µg/L	-	-
Nickel	µg/L	-	variable (hardness), 25[(T)]
Lead	µg/L	-	variable (DOC, hardness), 6.2[(D)]
Sulfur	mg/L	-	-
Antimony	µg/L	-	-
Selenium	µg/L	-	1[T]
Silicon	µg/L	-	-
Tin	µg/L	-	-
Strontium	µg/L	-	2,500[(D)]
Thorium	µg/L	-	-
Titanium	µg/L	-	-
Thallium	µg/L	-	0.8[T]
Uranium	µg/L	33[T]	15[T]
Vanadium	µg/L	-	120[(T)]
Tungsten	µg/L	-	-
Yttrium	µg/L	-	-
Zinc	µg/L	variable (hardness, DOC), 46[(D)]	variable (pH, hardness, DOC), 11[(D)]

Notes:
(T) Guideline applicable to Total metal concentration. (D) Guideline applicable to Dissolved metal fraction; mg/L = milligrams per litre; µg/L = micrograms per litre; DOC = dissolved organic carbon; TDS = total dissolved solids.

2.2.2 Background Water Quality

Background water quality terms have been derived as model inputs for surface water quality and groundwater quality. Surface water quality terms are based on measured water quality representative of the study area, which includes run-off from undisturbed areas (non-contact areas) as well as lakes and rivers surrounding the Project and extending to the outlet of Duley Lake. Background surface water quality source terms have been derived as mean values from measured data collected from June 2023 through October 2024 (Table 2-15). Data below the method detection limit are assumed to be half of the reported limit. The complete dataset with supporting statistics is reported in Appendix A. A summary of compiled data as applied to the model is provided here, with corresponding water quality monitoring locations provided in parentheses:

- non-contact run-off and Rose Pit/Rose Lake (WC-01)
- Pike Lake (PL-02NS/NB)
- Mills Lake (MIL-02NS/NB; MIL-03NS/NB)
- Waldorf River (WC-05)
- Riordan Lake and Rectangle Lake (RL-02NS/NB)
- Walsh River (WC-10)
- Duley Lake (LL-02NS/NB; LL-03NS/NB; LL-04NS/NB; LL-05NS/NB)
- Duley Lake outlet (WC-09)

Background surface water quality data are screened against applicable water quality guidelines (Table 2-14). Mean parameters that exceed the respective guidelines are shaded or shown in bold (Table 2-15) and include total mercury. Total mercury is above the guideline at all locations. Note the reported mercury concentrations are consistently below the method detection limit (Appendix A).

Background groundwater quality terms were derived from measured bedrock water quality reported in the Kami Project 2012 EIS (Alderon, 2012). Data were compiled from 15 separate bedrock monitoring wells with depths ranging from 1 to 48 m below surface. Median groundwater quality is applied to pit groundwater seepage terms (Table 2-16). Data below the method detection limit are assumed to be half of the reported limit. The compiled groundwater quality database is provided in Appendix B.

Background groundwater quality terms are applied as pit dewatering terms within the WBWQM. Parameters that are not measured from the background groundwater quality source terms (Table 2-16) are assigned values determined from background surface water quality for non-contact source terms (Table 2-15). Further, groundwater that originates from Pike Lake (*e.g.*, dewatered pit inflows) is assigned Pike Lake water quality, as determined in the model and as necessary to maintain conservation of mass balance.

Table 2-15: Background Surface Water Quality Source Terms

General Parameters	Unit	Pike Lake Inlet	Pike Lake	Mills Lake	Waldorf River	Riordan Lake	Walsh River	Duley Lake	Duley Lake Outlet
Alkalinity	mg/L as CaCO3	50.7	38	35.5	57.3	43.7	15.7	36.1	23.5

Yttrium	mg/L	nm
Zinc	mg/L	0.011

Notes: CACO3 = calcium carbonate; TDS = total dissolved solids; mg/L = milligram per litre; nm: Data not measured; GWQ = groundwater quality. Assumed dissolved concentration is equivalent to total for GWQ.

2.2.3 Geochemical Source Terms

Geochemical source terms were derived for Kami Project mine facilities and mine disturbance (contact) areas, including the OSP, MRS, Rose Pit highwall, and TMF rock embankment, and tailings (Appendix C).

Geochemical source terms are scaled to reflect Project development as a function of footprint consistent with the water balance (Section 2.1.5) and as a function of mine waste volume as relevant to mine rock and OSPs. Source terms are provided as concentrations and loading rates, consistent with the water balance.

Geochemical source terms are derived from geochemical characterization studies advanced by Okane (2024b, 2025) and informed by previous studies conducted by Stantec (2013). Geochemical testing includes static acid base accounting and metal content extractions as well as longer-term kinetic tests, which include ongoing kinetic programs. The acid generating potential and metal leaching potential for Kami mine rock units is generally low. Exceptions to this include the schist sub-unit of the Menihek Formation and to a lesser degree the Katsao Formation. These mine rock units are exclusive to the MRS and portions of the open pit highwall. Metal leaching potential associated with these units includes arsenic (As), cadmium (Cd), chromium (Cr), cobalt (Co), copper (Cu), iron (Fe), nickel (Ni), selenium (Se), uranium (U), and zinc (Zn).

All potentially acid generating (PAG) mine waste is managed within the MRS. Approximately 30% of mine waste within the MRS is classified as PAG or uncertain. MRS source terms assume PAG is well managed and blended to prevent locally acidic conditions. MRS source terms are coincidentally based on kinetic test data associated with neutral mine drainage (*e.g.,* non-acidic conditions).

Source terms for seepage from the OSP were derived from a single kinetic test and are therefore subject to uncertainty.

The metal leaching potential for tailings is low, consistent with operational experience in the region. Note, however, that iron oxidation processes associated with iron ore processing and tailings deposition, commonly referred to as red water, results in the weathering of iron and production of iron particulates (*e.g.,* iron hydroxides, rust) and associated TSS. Red water is a physical and chemical weathering phenomenon associated with the deposition of freshly processed tailings. An active water treatment facility (conventional sedimentation treatment) is proposed to manage TSS associated with excess water from the TMF prior to discharge to Duley Lake.

Source terms were also developed for nitrogen parameters (ammonia, nitrate, and nitrite) associated with blasting of mine rock and explosives residuals. In this regard nitrogen

source terms apply to actively developed pit walls blasted mine rock, including the mine rock stockpile and tailings embankment.

Additional contact water sources include sewage effluent from the Project. Sewage is managed in a tertiary biological treatment plant (BBA, 2024). Effluent discharge rates are consistent with potable water supply intake rates (250 m^3/d). Effluent from advanced (tertiary) treatment is suitable for direct discharge to the environment and is assumed to discharge directly to Duley Lake. Nitrate and ammonia concentrations in effluent from the sewage treatment plant are assumed to be 1 mg/L and 37.5 mg/L (as N), respectively (BBA 2024).

2.2.4 Duley Lake Conceptual Site Model

Duley Lake is the central receiver of mine effluent discharge from the Project. A conceptual site model of effluent mixing and dilution processes within Duley Lake has been developed to inform the water quality modelling approach (Appendix D).

Duley Lake attributes that inform the conceptual site model are summarized here:

- The bathymetry of Duley Lake has been well characterized. The lake has a volume of approximately 78 million cubic metres (Mm^3), an average depth of approximately 7.3 m, and a maximum depth of approximately 30 m.
- Duley Lake includes several sub-watersheds (Figure 2-1). The Walsh River system is the primary input that flows into the lake from the northwest. Other inputs to Duley Lake include Mills Lake and the Waldorf River from the south and Riordan Lake from the east.
- Excluding inputs from the Walsh River, the hydraulic residence time of the lake (volume/annual flow rate) is less than a year. Specifically, the lake water volume is replenished on approximately annual to monthly time scales relative to the inputs.
- Lake temperature and density observations demonstrate that summer stratification occurs. Seasonal turnover occurs at least twice per year, resulting in vertical mixing of the lake water column. Vertical mixing is also facilitated by wind during the open water season (May through October).
- Lake velocities are influenced by wind (Figure 2-21) and lake bathymetry. Changes in wind direction and wind speed will influence lake velocities and directions during the open water season and will facilitate vertical and horizontal mixing.
- During ice cover in winter, lake velocities will be hydraulically controlled and will be very low relative to the open water period.

- Mine effluent will be disharged to the central portion of the lake at depth via a pipeline from the mill (Figure 2-22). An end-of-pipe diffusor has been designed to facilitate near-field mixing of effluent with ambient conditions within the lake (Figure 2-23).

The maximum concentration of effluent in the lake is the ambient concentration the lake plus the concentration due to the effluent discharge plume. The ambient lake concentration is determined as a function of the lake inflows and outflows. Near the diffuser, the effluent dilution (mixing with ambient lake water) is efficiently diluted with lake water as a function of the diffuser parameters (geometry, flow rate, density) and ambient lake conditions (currents, stratification). Moving away from the diffuser, ambient lake conditions entirely control the fate of the plume. The zone where the diffuser parameters control the plume dynamics is called the near field zone (NFZ). The zone where lake ambient conditions control the plume dynamics is the far field zone (FFZ). In the FFZ, concentrations decrease to ambient lake values.

The modelling of lake concentrations is conducted as a two-step process. First, ambient lake concentrations (FFZ) are simulated based on the overall mass balance (Figure 2-23) as follows:

$$V^{lake}\frac{\partial C^{lake}}{\partial t} = Q_{in}^{rivers}C_{in}^{rivers} + Q_{in}^{mine}C_{in}^{mine} - Q_{out}^{lake}C_{out}^{lake} \qquad (Equation\ 1)$$

Where V^{lake} is the lake volume (78 million m^3), C is the effluent concentration of a particular parameter and Q is the corresponding flow rate. Equation 1 states that the change of ambient concentration (the term on the left-hand side) is a function of the inflow flow rates and concentrations. The outflow concentration is equal to the ambient lake concentration (well-mixed lake). Simulations of ambient lake concentrations for Duley Lake conservatively exclude inputs from Walsh River, which is a potentially important source of dilution. Including inputs from Walsh River would increase the dilution of Project effluent by a factor of approximately three to five (Appendix D). Contributions from Walsh River are, however, included in the determination of Duley Lake outlet concentrations (Q^{lake}_{outlet}).

Simulations of NFZ concentrations downgradient of the diffusor are simulated with the CORMIX software (Jirka *et al*. 1991). Minimum dilution ratios at the centre of the effluent plume 100 m from the diffuser are determined for a range of mine effluent discharge rates for three seasonal lake scenarios:

- **Spring/fall**—The lake is homogeneous at a density of 4°C; the currents are 2 cm/s. The effluent is fresh water at 4°C.

- **Summer**—The lake is stratified with an 8 m thick epilimnion at 17°C and a hypolimnion at 7°C. The currents are 2 cm/s. The effluent is fresh water at 17°C.
- **Winter**—The lake is ice covered (1 m thick ice) and reversely stratified with a 1 m thick epilimnion at 1°C and a hypolimnion at 4°C. The currents are 0.04 mm/s. The effluent is fresh water at 4°C.

Minimum dilution ratio tables were derived as a function effluent flow rate for each season as inputs to the WBWQM (Appendix D). Dilution ratios are applied in the WBWQM to determine Duley Lake Initial Dilution Zone (IDZ) concentrations as follows:

$$C = \frac{C_{amb} \times d + C_{eff} \times 1}{(d + 1)} \quad (Equation\ 2)$$

Where C_{amb} is the ambient lake concentration determined for the FFZ (Equation 1), C_{eff} is the effluent concentration and d is the calculated dilution. Model results for the NFZ as described above are reported as the Duley Lake IDZ.

Duley Lake water quality simulations assume a fully mixed lake, informed by catchment and seasonal scale processes that promote mixing on reasonably long-time scales (greater than one year) relative to the hydraulic residence time of the lake (less than one year). However, at a particular location and on shorter time scales, lake dynamics will lead to fluctuations around the simulated values. During spring and fall turnover, the lake will be vertically homogeneous, and the wind should efficiently mix the lake horizontally, leading to a well-mixed lake and ambient concentration consistent with model simulations throughout the lake except near inputs to the lake and near the diffusor.

Note: See Appendix D for formula terms.

2.2.5 Water Quality Model Outputs

Consistent with the water balance, water quality model outputs are produced for all phases and periods of the Project, including Construction (Year -1), Operations (Year 0 through Year 24), Closure (Year 25 through Year 36), and Post-closure (Year 37 through Year 73). Three selected flow scenarios are simulated based on annual precipitation (Figure 2-12). The selected model scenarios are as follows:

1) MAP, representing one of the climate year closest to the MAP value of 890 mm (2016)
2) 25th percentile (P25), corresponding to the climate year closest to the 25th percentile of the precipitation record at 780 mm (1994)
3) 75th percentile (P75), representing the climate year closest to the 75th percentile of the precipitation record at 960 mm (2014)

These are the water quality model outputs by phase and period:

- Mine discharge (Operations)
  - Mine Effluent (combined discharge from Pit collection pond and TMF)
- Receiving environment
  - Duley Lake IDZ (Operations)
  - Duley Lake (Operations, Closure, and Post-closure)
  - Duley Lake Outlet (Operations, Closure, and Post-closure)
  - Pike Lake (Operations, Closure, and Post-closure)
  - Walsh River (Operations, Closure, and Post-closure)
  - Rose Pit Lake (Post-closure)
  - Mills Lake (Post-closure)
  - Waldorf River (Post-closure)
  - Riordan Lake (Post-closure)
  - Rectangle Lake (Post-closure).

3. Water Balance Model Results

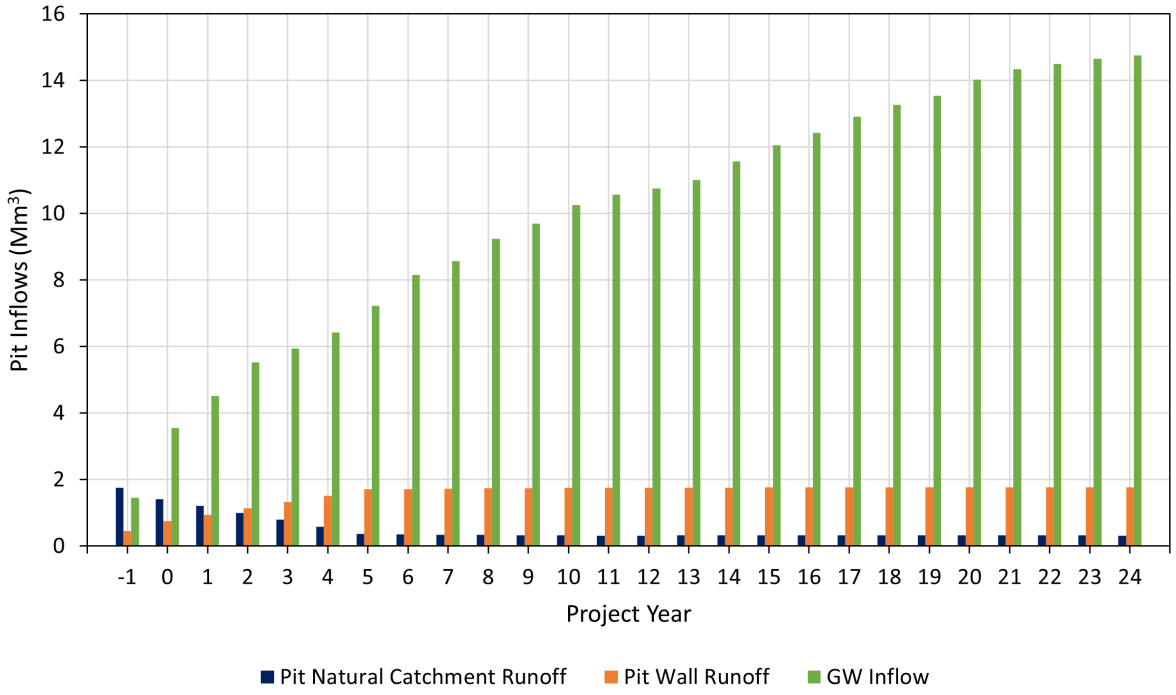
3. Water Balance Model Results

This section presents the results of the Kami WBM, with a focus on the water balances of the Rose Pit, Pit collection pond, Duley Lake and Pike Lake during the active mining and closure phases. While the majority of the WBM results are presented for the MAP model scenario, some results are also included for the P25 and P75 scenarios for comparison. Complete water balance results for all phases, time steps, and flow scenarios are provided in Appendix E.

3.1 Rose Pit

During Construction and Operations, flows into the open pit include direct precipitation, surrounding undiverted natural catchment run-off, pit wall run-off, and groundwater inflow. As the pit develops, pit natural catchment (non-contact) run-off decreases, while the pit wall run-off increases until Year 10 (Figure 3-1), when the pit wall reaches its maximum area (Table 2-9). The predicted groundwater inflow to the pit shows a consistent upward trend throughout Operations, reaching 14.8 Mm^3 at the end of Operations for the MAP scenario (Table 2-10 and Figure 3-1). The pit sump is dewatered into the Pit collection pond.

Figure 3-1: Time Series of Predicted Annual Flows to Pit during Construction and Operations Based on the MAP Scenario



Note: Mm^3 = million cubic metres; GW = groundwater.

Once the Operations phase is over, the model predicts that the pit water elevation will reach the spillway elevation within approximately 10 years based on the MAP model scenario, resulting in complete pit flooding (Figure 3-2), with the active water transfers from Duley Lake, TMF pond and stockpile collection ponds. By the end of Closure, the pit bottom layer will have a volume of 62 Mm^3 for the MAP model scenario, corresponding to a water elevation of 385 m (Figure 3-2). The majority (73%) of the bottom layer at the end of Closure is composed of MRS seepage, followed by OSP run-off (18%) and then GW inflow (9%).

The primary inflow to the surface pit layer is the water transfer from Duley Lake, ranging from 15 Mm^3 to 26 Mm^3 per year (Table 3-1). This is followed by the transfers from the TMF pond and natural catchment run-off. In addition to the water transfers, the surface layer receives pit wall run-off and groundwater inflow. As the pit floods, the water level in the pit increases, leading to a reduction in exposed pit wall area and, therefore, volumes of pit wall run-off. Concurrently, the total predicted annual GW Inflow to the Rose Pit decreases rapidly from 14.8 Mm^3 at the end of Operations (Figure 3-1) to 4.3 Mm^3 (distributed equally between bottom and upper layers) in Year 25 (first year of Closure) (Table 3-1), then further decreases to 1.8 Mm^3 in Year 26 (Table 3-1), based on the relationship between GW inflow and water elevation in the flooded pit (Table 2-11).

Table 3-1: Mean Annual Inputs to the Flooded Rose Pit through Closure

Project Year	Pit Surface Layer						Pit Bottom Layer			
	Transfers from Duley Lake (Mm^3)	Transfers from TMF Pond (Mm^3)	Pit Wall Run-off (Mm^3)	GW Inflow (Mm^3)	Natural Run-off[(a)] (Mm^3)	Total Inflow (Mm^3)	OSP Run-off (Mm^3)	MRS Seepage (Mm^3)	GW Inflow (Mm^3)	Total Inflow (Mm^3)
25	23.21	7.30	1.58	2.16	2.20	36.45	0.97	3.80	2.16	6.93
26	24.72	6.57	1.37	0.91	2.56	36.14	0.98	3.82	0.91	5.70
27	25.11	6.08	1.22	0.59	2.81	35.81	0.98	3.80	0.59	5.37

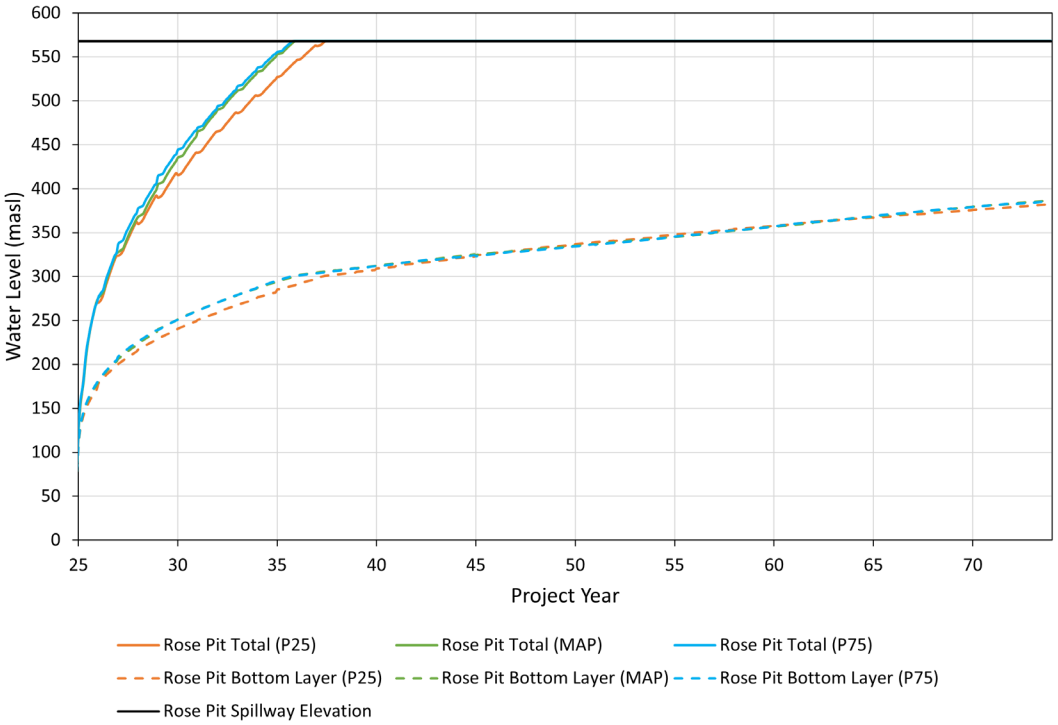
31	25.68	6.06	0.81	0.20	4.40	37.16	0.98	3.83	0.20	5.01
32	25.75	6.06	0.73	0.16	4.53	37.23	0.98	3.84	0.16	4.99
33	25.82	6.03	0.65	0.10	4.66	37.26	0.99	3.84	0.10	4.93
34	26.04	6.06	0.57	0.00	4.79	37.46	0.99	3.86	0.00	4.85
35	26.03	6.03	0.50	0.00	4.88	37.45	0.99	3.84	0.00	4.83
36	15.42	3.42	0.39	0.00	4.40	23.63	0.63	3.28	0.00	3.91
Total	294.15	71.84	10.80	5.14	46.45	428.37	11.42	45.37	5.14	61.93

Notes: **(a)** Natural run-off includes pit natural catchment run-off, direct precipitation over the pit lake surface, and stockpile natural catchment run-off.

Mm^3 = million cubic metres; TMF = tailings management facility; OSP = overburden stockpile; MRS = mine rock stockpile; GW = groundwater.

During Post-closure, the pit bottom layer continues to receive MRS seepage (approximately 2.3 Mm³/yr), causing the elevation of the pit bottom layer to rise throughout this phase (Figure 3-2). By the end of Post-closure, the pit bottom layer elevation is expected to range from 382 to 387 masl, depending on the model scenario (Figure 3-2). At the same time, the surface layer, which receives direct precipitation, pit wall run-off, and pit lake natural catchment run-off, is predicted to reach a depth of 181 to 186 masl by the end of the Post-closure period (Figure 3-2).

Figure 3-2: Time Series of Predicted Pit Water Levels during Closure and Post-closure for MAP, P25, and P75 Scenarios



Notes: masl = metres above sea level; MAP = mean annual precipitation.

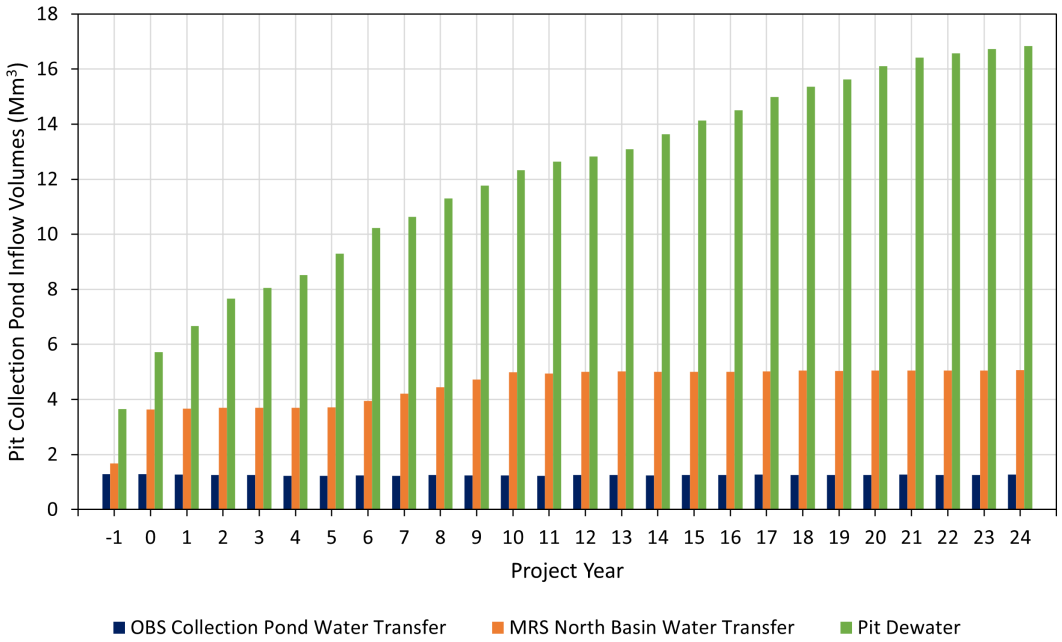
3.2 Pit Collection Pond

The primary flow to the Pit collection pond comes from pit dewatering, which accounts for approximately 73% of the total inflow for the MAP scenario at the end of Operations (Year 24), when the Project footprint reaches the maximum planned extent (Figure 3-3 and Table 3-2). The volume of pit dewatering is primarily driven by pit groundwater inflow, which increases as the pit develops, reaching 40,430 m³/d (about 14.8 Mm³; Table 2-10) in Year 24. This groundwater inflow accounts for about 73% of the total dewater volume for the MAP scenario in Year 24.

Water transferred from the MRS North collection pond is the second major inflow to the Pit collection pond. The transfer rate increases as the MRS footprint expands, reaching

around 5 Mm^3 in Year 10, when the MRS footprint reaches its final extent. After Year 10, the MRS collection pond transfer rate slightly increases, which is mostly driven by the increased precipitation. The annual water transfer from the OSP collection pond remains around 1.3 Mm^3 throughout Construction and Operations (Figure 3-3).

Figure 3-3: Time Series of Predicted Major Annual Mine Flows to Pit Collection Pond during Construction and Operations Based on the MAP Scenario



Notes: Mm^3 = million cubic metres; OSP = overburden stockpile; MRS = mine rock stockpile.

Table 3-2: Predicted Monthly Mine Flows to Pit Collection Pond at End of Operations Based on the MAP Scenario

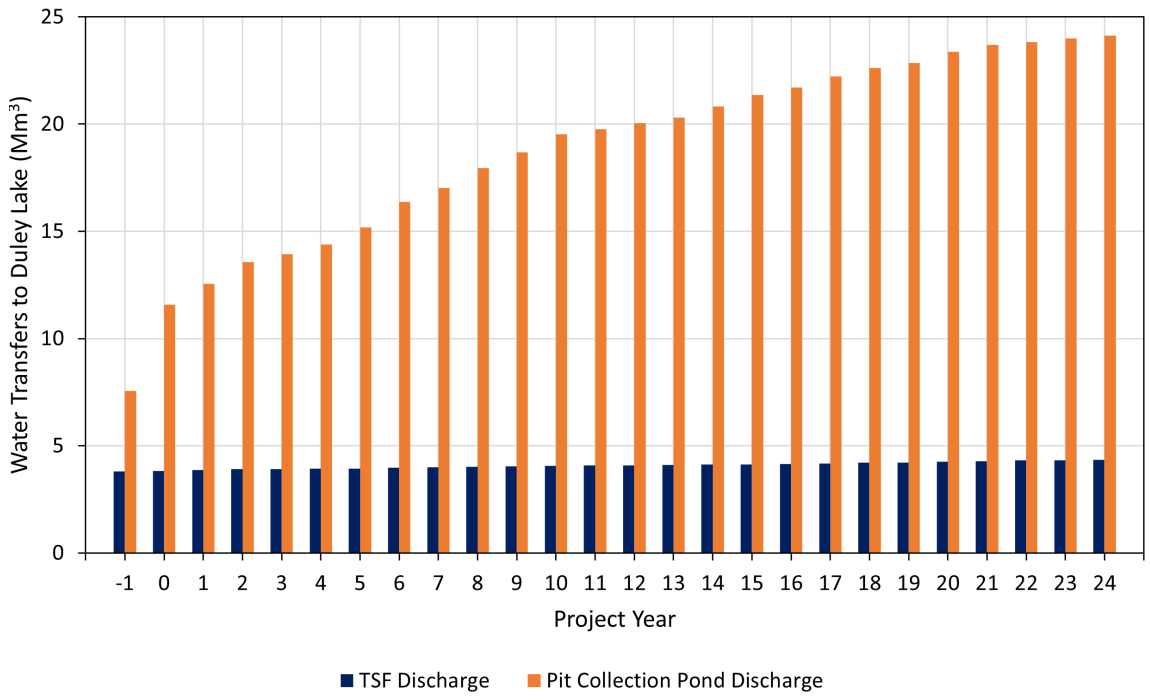
Month	Pit Dewatering (Mm^3)	MRS North Collection Pond Water Transfer (Mm^3)	OSP Collection Pond Water Transfer (Mm^3)
January	1.26	0.33	0.10
February	1.14	0.31	0.07
March	1.25	0.35	0.09
April	1.33	0.37	0.08
May	1.89	0.68	0.17
June	1.52	0.54	0.13
July	1.51	0.44	0.11
August	1.47	0.43	0.11
September	1.39	0.43	0.10
October	1.48	0.41	0.11
November	1.36	0.41	0.11
December	1.26	0.35	0.09
Total	**16.84**	**5.07**	**1.27**

Notes: Mm^3 = million cubic metres; MRS = mine rock stockpile; OSP = overburden stockpile.

3.3 Duley Lake

Water transfers from Pit collection pond to Duley lake increase over time as the stockpile footprints grow and the open pit develops (Figure 3-4). It is important to highlight that the transfer rates from the Pit collection pond are primarily influenced by the pit dewatering inflows into the pond, as shown in Figure 3-3. At the end of Operations, the model predicts annual discharge from the Pit collection pond to Duley Lake reaching 24 Mm^3 for the MAP scenario, with the highest monthly discharge occurring in May (Table 3-3). The annual discharge rate from the TMF pond to Duley Lake is predicted to remain relatively stable throughout Operations, around 4 Mm^3, as the model assumes that the TMF is fully built at the start of Operations.

Figure 3-4: Time Series of Predicted Annual Discharges from Tailings Management Facility and Pit Collection Pond to Duley Lake during Construction and Operations, Based on the MAP Scenario



Notes: Mm^3 = million cubic metres; TMF = tailings management facility.

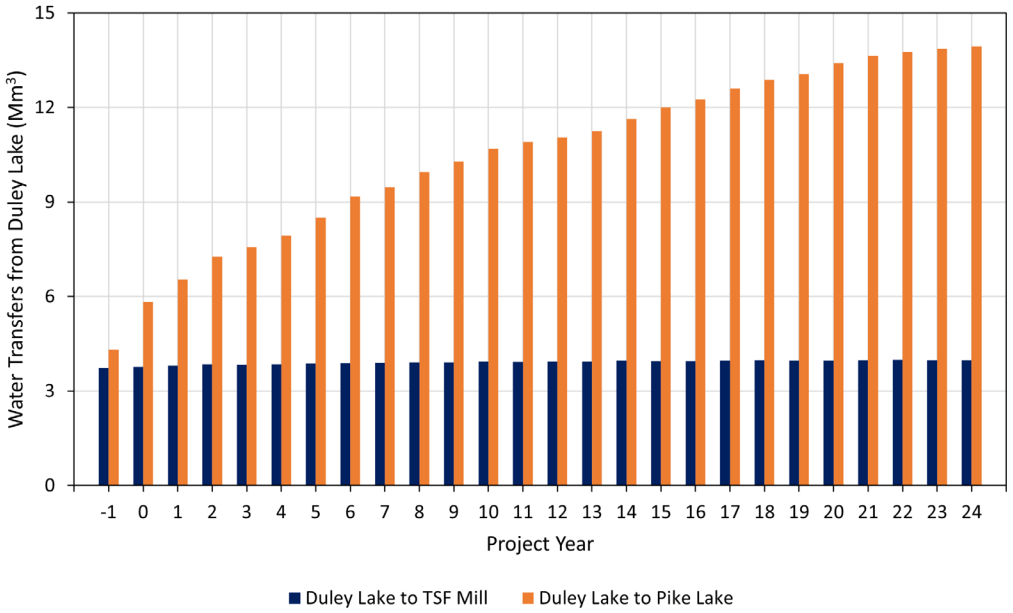
Table 3-3: Predicted Monthly Tailings Storage Facility and Pit Collection Pond Discharges to Duley Lake at the End of Operations for the MAP Scenario

Month	TMF Discharge (Mm^3)	Pit Collection Pond Discharge (Mm^3)	Total Discharge (Mm^3)
January	0.33	1.70	2.03
February	0.21	1.52	1.73
March	0.09	1.70	1.79
April	0.07	1.82	1.89
May	0.44	3.04	3.48
June	0.45	2.34	2.79
July	0.47	2.15	2.61
August	0.47	2.09	2.56
September	0.45	2.00	2.45
October	0.47	2.08	2.54
November	0.45	1.97	2.42
December	0.47	1.72	2.19
Total	**4.34**	**24.12**	**28.46**

Notes: Mm^3 = million cubic metres; TMF = tailings management facility.

As the open pit develops and groundwater seepage from Pike Lake to the pit increases over time, the amount of water transferred from Duley Lake to Pike Lake to maintain discharge rates above the threshold also rises (Figure 3-5). By the end of Operations, the model predicts monthly transfer rates from Duley Lake to Pike Lake ranging from 0.9 to 1.3 Mm^3, with the annual transfer rate reaching approximately 14 Mm^3 (Table 3-4).

Figure 3-5: Time Series of Predicted Annual Water Transfers from Duley Lake to Process Plant and to Pike Lake during Construction and Operations, Based on the MAP Scenario



Notes: Mm^3 = million cubic metres; TSF Mill = tailing management facility and process plant.

During Operations, fresh water required for mill operations is drawn from Duley Lake at a relatively constant rate of around 4 Mm^3 (Figure 3-5), with monthly transfers reaching about 0.3 Mm^3 by the end of Operations (Table 3-4). It is important to highlight that the fresh water drawn from Duley Lake accounts for roughly 30% of the total mill inflow demand, with the remaining 70% supplied by recycled water from the TMF.

Table 3-4: Predicted Monthly Water Transfers from Duley Lake to Pike Lake and to Tailings Storage Facility Mill at the End of Operations for the MAP Scenario

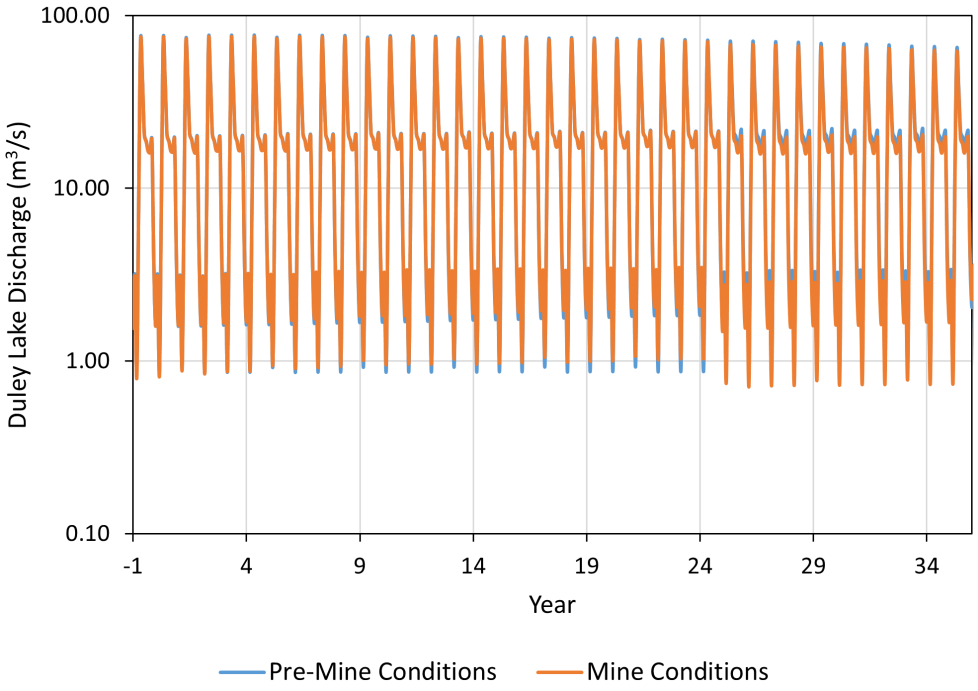
Month	Duley Lake Transfer to Pike Lake (Mm^3)	Duley Lake Transfer to TMF Mill (Mm^3)
January	1.01	0.34
February	0.91	0.31
March	1.01	0.32
April	0.97	0.29
May	1.30	0.34
June	1.26	0.33
July	1.31	0.34
August	1.31	0.34
September	1.26	0.33
October	1.31	0.34
November	1.26	0.33
December	1.02	0.34
Total	**13.94**	**3.98**

Notes: Mm^3 = million cubic metres; TMF = tailing management facility.

Predicted alterations to the pre-mine streamflow regime at Duley Lake Outlet during Operations (Figure 3-6) are linked to 1) the removal of contributing areas within the proposed mine site (Table 2-2); 2) water transfers from the Pit collection pond to Duley Lake (Figure 3-4); and 3) water withdrawals from Duley Lake, mainly for Pike Lake and TMF mill (Figure 3-5; Table 3-4). While the removal of contributing areas and the water withdrawals from Duley Lake are expected to reduce the lake discharge compared to the pre-mine conditions, the water transfers from the Pit collection pond to Duley Lake are anticipated to offset these declines.

For the MAP model scenario, the largest relative changes in streamflow regime at the Duley Lake outlet during Operations are expected to occur in winter months, with monthly discharge rates projected to be 6% to 18% higher than pre-mine conditions, depending on the month (Table 3-5). During the open water season, the Project's impact on lake discharge is predicted to be minimal, with a projected relative increase of 0% to 2% in monthly discharge by the end of Operations (Table 3-5). Overall, the annual average discharge at the Duley Lake outlet at the end of Operations is projected to be 1% lower than the pre-mine conditions (Table 3-5).

Figure 3-6: Time Series of Predicted Monthly Duley Lake Discharge (in log scale) under Pre-mine versus Mine Conditions for the MAP Scenario during Construction, Operations and Closure



Note: Mm^3 = million cubic metres.

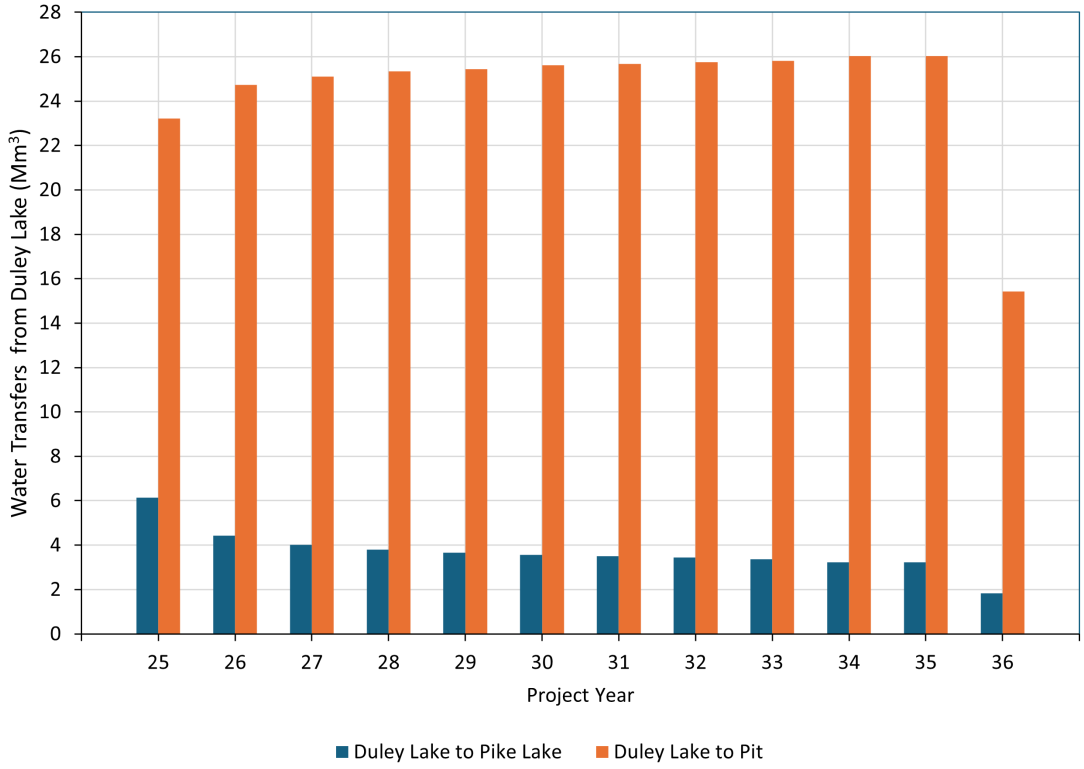
Table 3-5: Predicted Monthly Duley Lake Average Discharge under Pre-mine vs. Mine Conditions for the MAP Scenario for End of Mine (Year 24)

Month	Pre-mine Conditions (m^3/s)	Mine Conditions (m^3/s)	Project Impact (%)
January	1.8	2.1	12%
February	3.3	3.4	5%
March	0.9	1.0	18%
April	10.5	10.5	0%
May	68.5	67.3	-2%
June	40.0	39.4	-1%
July	21.0	20.9	0%
August	19.6	19.5	0%
September	17.3	17.2	0%
October	18.8	18.7	0%
November	21.2	21.1	-1%
December	4.0	4.2	6%
Average	**18.9**	**18.8**	**-1%**

Note: m^3/s = cubic metres.

During Closure, the transfer of water from Duley Lake to Pike Lake is predicted to continue, with a maximum of 6 Mm³ in the first year of closure for the MAP scenario (Figure 3-7). This rate is lower than during Operations due to reduced groundwater seepage losses from Pike Lake as the pit floods. Additionally, Duley Lake is pumped to the pit to speed up the flooding process, reaching a maximum of 26 Mm³ by Year 35 for the MAP scenario (Figure 3-7).

Figure 3-7: Time Series of Predicted Annual Water Transfers from Duley Lake to Pike Lake and to Pit for the Closure Phase, Based on the MAP Scenario



Note: Mm³ = million cubic metres.

Water transfers from Duley Lake to Pike Lake and to the Rose Pit during Closure are predicted to result in a decrease in monthly discharges at the Duley Lake outlet by 4% to 16% compared to pre-mine conditions under the MAP scenario, with the largest decreases anticipated during winter months (Table 3-6). On an annual basis, the Project is predicted to lead to an average 7% reduction in Duley Lake discharge during Closure relative to pre-mine conditions for the MAP scenario (Table 3-6).

Table 3-6: Predicted Monthly Average Discharge at Duley Lake Outlet under Pre-mine versus Mine Conditions for the MAP Scenario during Closure Phase (years 25 through 36)

Month	Pre-mine Conditions (m^3/s)	Mine Conditions (m^3/s)	Project Impact (%)
January	2.0	1.7	-16%
February	3.3	2.9	-12%
March	0.9	0.8	-14%
April	11.3	10.3	-9%
May	65.0	62.2	-4%
June	39.4	37.2	-5%
July	21.1	19.5	-8%
August	19.9	18.3	-8%
September	17.5	16.1	-8%
October	19.2	17.9	-7%
November	21.5	19.9	-8%
December	4.1	3.5	-14%
Total	**18.8**	**17.5**	**-7%**

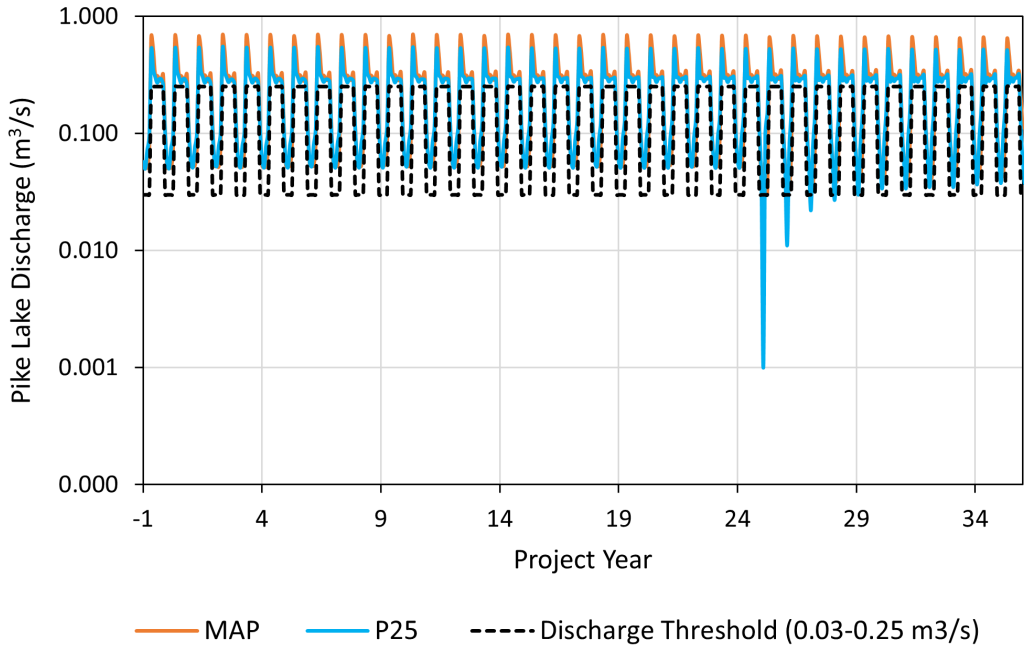
Note: m^3/s = cubic metres per second.

3.4 Pike Lake

To mitigate the impacts of the removal of contributing catchment areas within the proposed mine site and groundwater seepage from Pike Lake into the open pit on lake discharges, water is transferred from Duley Lake to Pike Lake during both the Operations phase (Figure 3-5) and the Closure phase (Figure 3-7).

Under the MAP scenario, Pike Lake discharge is expected to remain above the seasonal minimum discharge threshold rates (0.03 m^3/s for December to April and 0.25 m^3/s for May to November) established by MacCarthy (2024) (Figure 3-8). However, in the P25 scenario, Pike Lake discharge rates are projected to fall below the minimum threshold during the winter months in the early years of the Closure phase coincident with pit filling (Figure 3-8). It is important to note that during the pit filling period, the total transfer rate from Duley Lake to Pike Lake and to the pit is limited by the pump capacity assumptions in addition to water availability in Duley Lake. While increasing the transfer rate from Duley Lake to Pike Lake could help prevent discharge from dropping below the threshold, it might also prolong the pit filling process.

Figure 3-8: Time Series of Predicted Monthly Pike Lake Discharge (in log scale) for MAP and P25 Scenarios during the Construction, Operations, and Closure Phases, Compared to the Seasonal Minimum Threshold Discharge Rates Established by WSP (0.03 m^3/s for December to April and 0.25 m^3/s for May to November)



Notes: m^3/s = cubic metres per second; MAP = mean annual precipitation.

4. Water Quality Model Results

4. Water Quality Model Results

Water quality model results for the Project are presented in the following section and include water quality screening to identify POPCs. Summary plots of relevant POPCs are presented for all Project phases and flow scenarios consistent with WBM results (Section 3). Complete water quality results for all phases, time steps, and flow scenarios with corresponding water quality guidelines are provided in Appendix F.

4.1 Water Quality Screening

Water quality model simulations of Project effluent concentrations were below MDMER discharge standards (Table 2-13) for all phases and periods.

Model simulations of concentrations in receiving environment water bodies were compared to applicable ambient aquatic water quality guidelines (Table 2-14) for all Project phases to screen out and identify POPCs for further analysis and assessment. Note that some guidelines are variable and are based on dependent parameters (e.g., hardness, dissolved organic carbon (DOC), pH, and temperature). Ambient conditions were assumed for dependent parameters as follows:

- pH: 7.5 standard units
- DOC: 2.5 mg/L
- Temperature: 8.5 degrees Celsius (copper) or 20 degrees Celsius (ammonia)
- Hardness: calculated from modelled calcium and magnesium

Water quality screening was conducted for all phases of the Project and for all flow months (P25, MAP, and P75). Screening of model simulations of receiving environment water quality are summarized by Project phase (Table 4-1). A parameter or constituent that exceeds the respective CCME or FWQG is denoted with "CCME" (Table 2-14). As stated previously (Section 2.2.1), aquatic life water quality guidelines are used to identify POPCs in the receiving environment. Aquatic life water quality guidelines do not apply to site discharges. POPCs are defined as Project-related effects that occur above the respective aquatic life water quality guideline and include cobalt and selenium. Complete model results for these parameters are presented below to inform the environmental assessment.

Table 4-1: Canadian Council of Ministers of the Environment (CCME) Exceedance Summary Table for Receiving Enviroment Model Nodes

Station	Phase	Construction			Operations			Closure			Post-closure		
	Model Scenario	P25	MAP	P75	P25	MAP	P75	P25	MAP	P75	P25	MAP	P75
Duley Lake IDZ	Cobalt_Total	-	-	-	CCME	CCME	CCME	-	-	-	-	-	-

Note:CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

4.2 Simulated Constituents of Interest

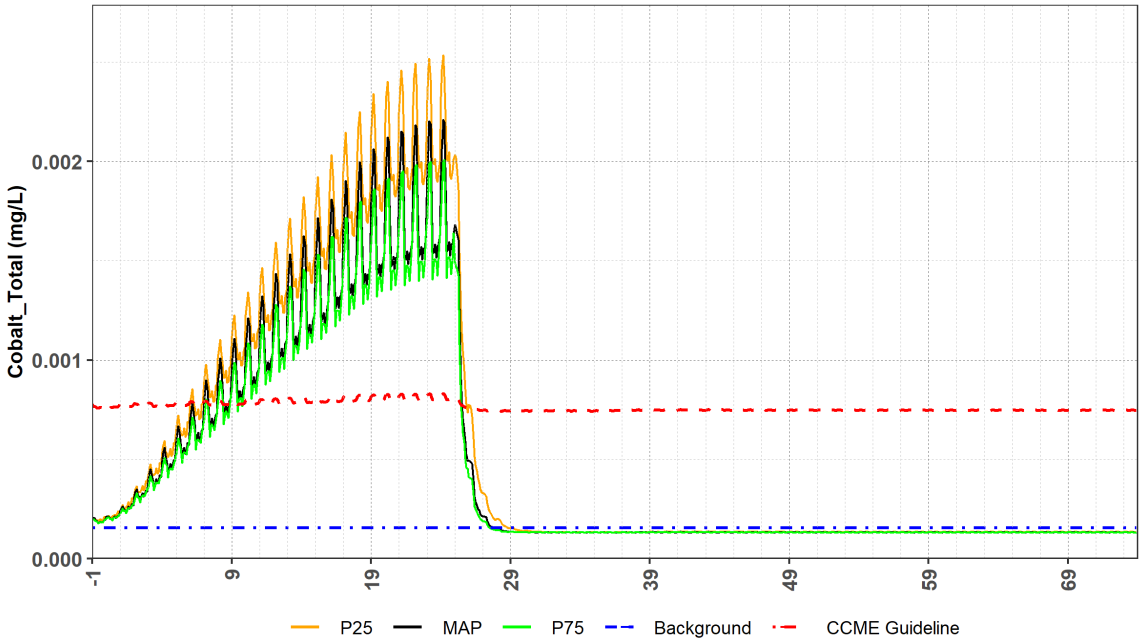
Water quality model results for POPCs are presented by model node as identified from the water quality screening summary (Table 4-1). POPCs include cobalt and selenium. Time series plots illustrate the Project effect on POPCs for all phase of the Project as monthly results for the P25, MAP, and P75 flow scenarios. Time series plots also include respective water quality guidelines (Table 2-14) and background water quality to facilitate interpretation. Time series plots of hardness are also included to inform the hardness-dependent guideline (Table 2-14), and to inform the Project effects assessment.

4.2.1 Duley Lake Initial Dilution Zone

Duley Lake IDZ simulations represent the centre of the effluent discharge plume approximately 100 m from the diffuser (Section 2.2.4). Project effects on total cobalt at the Duley Lake IDZ exceed the CCME guideline during the Operations phase of the Project beginning in approximately Year 9 (Figure 4-1). Project effects on total cobalt are reversible and do not persist beyond operations. Project effects on hardness at the Duley Lake IDZ are included to inform the corresponding guidelines and associated effects assessment (Figure 4-2).

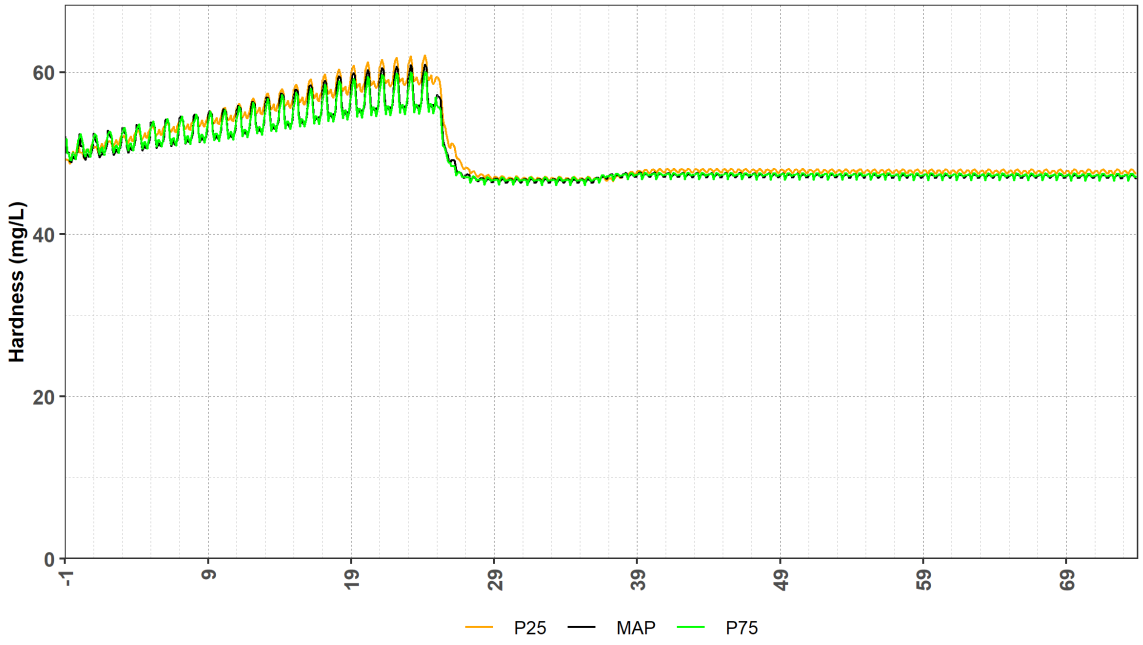
Project effects on total selenium at the Duley Lake IDZ exceed the CCME guideline during the Operations phase of the Project beginning in approximately Year 13 (Figure 4-3) Project effects on total selenium are reversible and do not persist beyond operations.

Figure 4-1: Time Series of Modelled Predictions of Total Cobalt for P25, MAP, and P75 Model Scenarios for Duley Lake IDZ



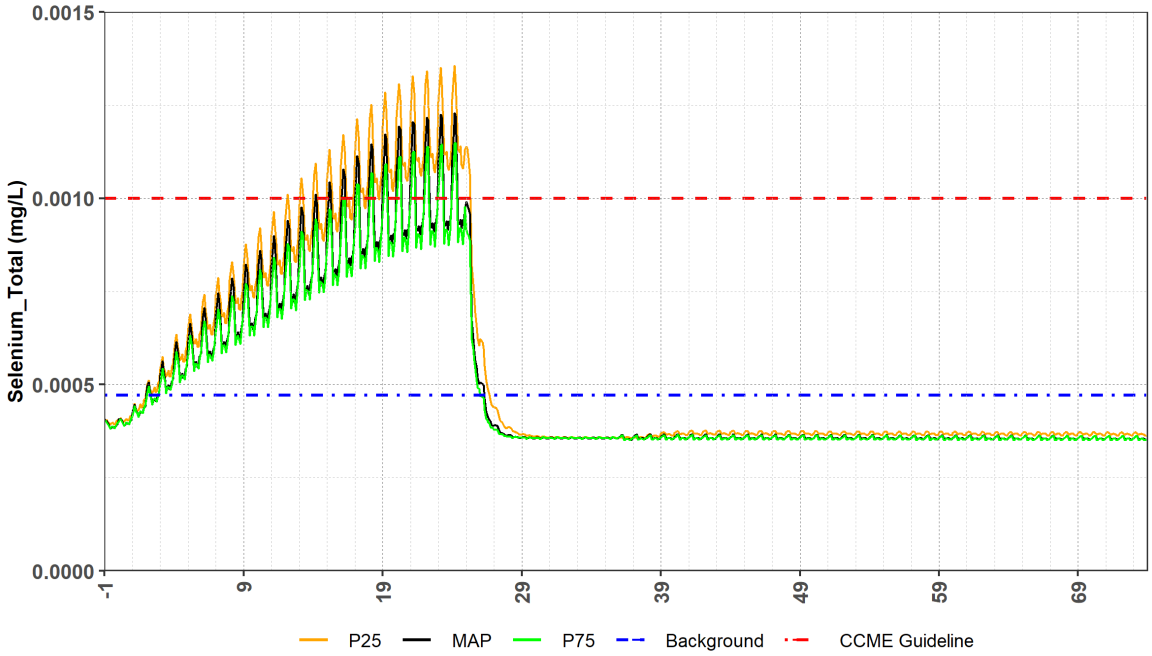
Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation; IDZ = initial dilution zone.

Figure 4-2: Time Series of Modelled Predictions of Hardness for P25, MAP, and P75 Model Scenarios for Duley Lake IDZ



Notes: mg/L = milligrams per litre; MAP = mean annual precipitation; IDZ = initial dilution zone.

Figure 4-3: Time Series of Modelled Predictions of Total Selenium for P25, MAP, and P75 Model Scenarios for Duley Lake IDZ



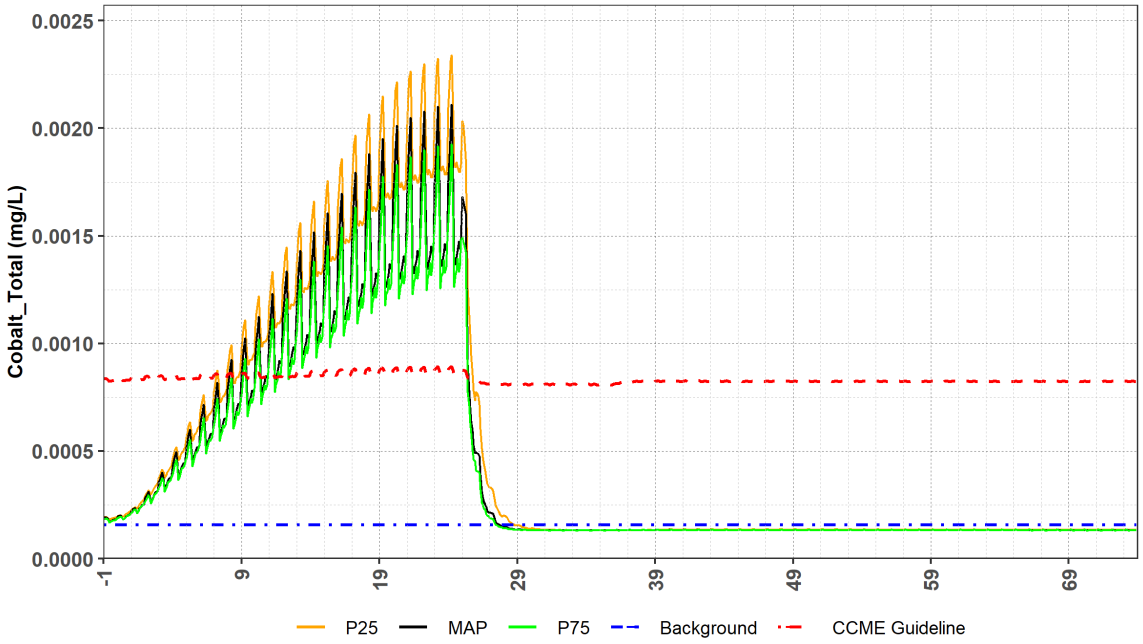
Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation; IDZ = initial dilution zone.

4.2.2 Duley Lake

Duley Lake simulations represent ambient conditions due to effluent discharge from the Project. Project effects on Duley Lake are similar to but slightly lower than the Duley Lake IDZ due to mixing processes that occur within the lake (Section 2.2.4). Project effects on total cobalt in Duley Lake exceed the CCME guideline during the Operations phase of the Project beginning in approximately Year 9 (Figure 4-4). Project effects on total cobalt are reversible and do not persist beyond operations. Project effects on hardness in Duley Lake are included to inform the corresponding guidelines and associated effects assessment (Figure 4-5).

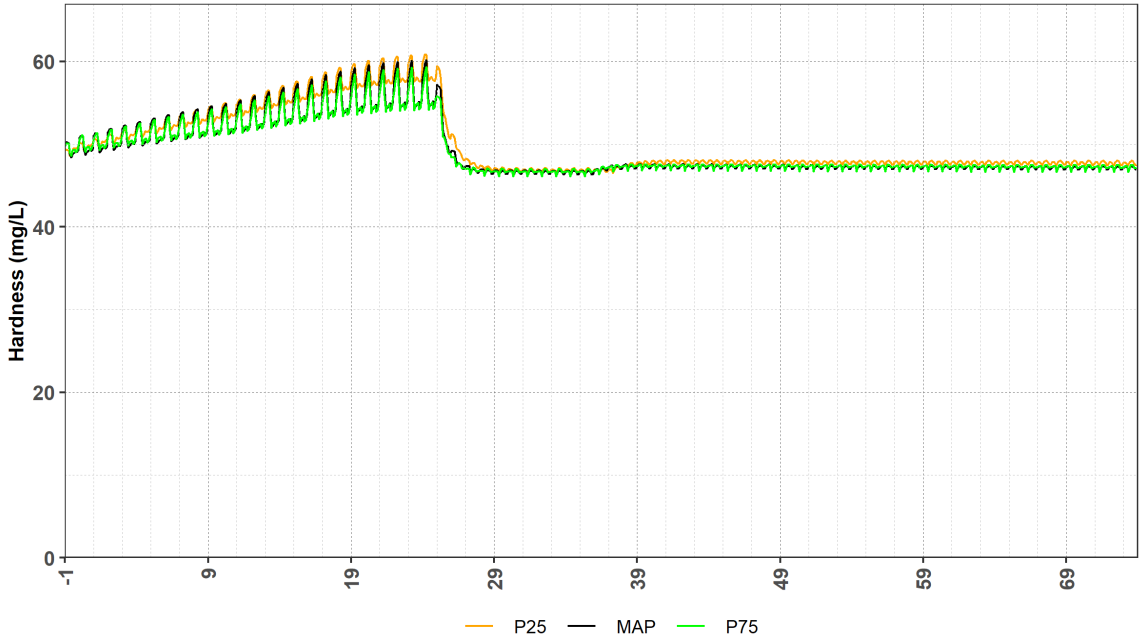
Project effects on total selenium at the Duley Lake IDZ exceed the CCME guideline during the Operations phase of the Project beginning in approximately Year 16 (Figure 4-6). Project effects on total selenium are seasonal, reversible, and do not persist beyond operations.

Figure 4-4: Time Series of Modelled Predictions of Total Cobalt for P25, MAP, and P75 Model Scenarios for Duley Lake



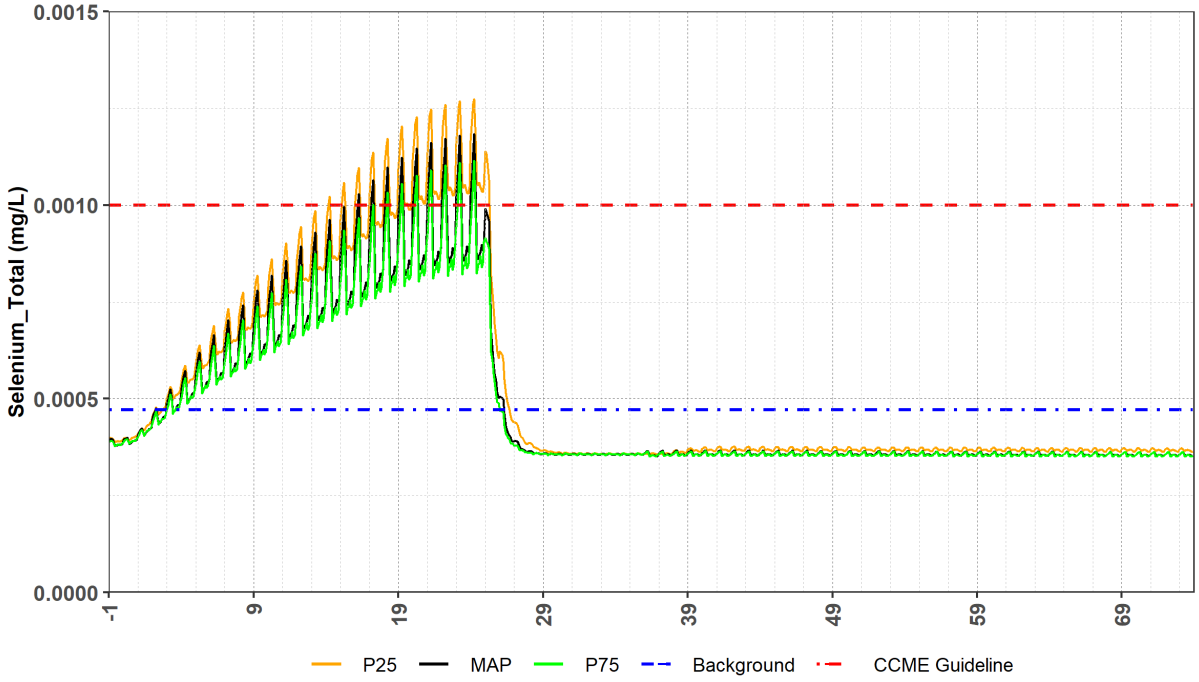
Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

Figure 4-5: Time Series of Modelled Predictions of Hardness for P25, MAP, and P75 Model Scenarios for Duley Lake



Notes: mg/L = milligrams per litre; MAP = mean annual precipitation.

Figure 4-6: Time Series of Modelled Predictions of Total Selenium for P25, MAP, and P75 Model Scenarios for Duley Lake



Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

4.2.3 Pike Lake

Project effects on Pike Lake are distinct for Operations phase and Post-closure period of the Project. Project effects during Operations are associated with transfers from Duley Lake (and associated effects on ambient Duley Lake water quality of Project effluent discharges). Water transfers to Pike Lake are required to meet water demands associated with pit dewatering and potential groundwater effects on Pike Lake water levels. Water transfers are governed by Pike Lake discharge rates, as required, to prevent effects on fish and fish habitat within and downgradient of Pike Lake (Section 3.4).

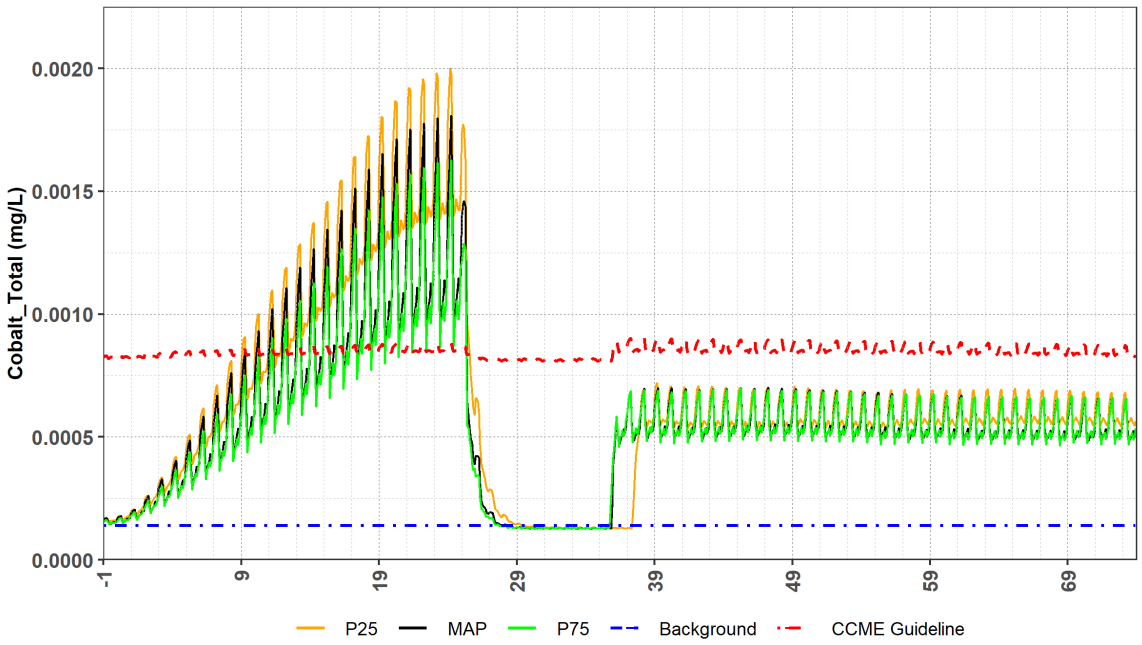
Project effects on Pike Lake during Post-closure are primarily due to passive seepage from the OSP.

Pike Lake simulations represent ambient conditions within the lake. Project effects on total cobalt in Pike Lake exceed the CCME guideline during the Operations phase of the Project beginning in approximately Year 11 (Figure 4-7). Project effects on total cobalt are reversible and do not persist beyond operations. Project effects on hardness in Duley Lake are included to inform the corresponding guidelines and associated effects assessment (Figure 4-8).

Project effects on total selenium in Pike Lake seasonally exceed the CCME guideline during the Operations phase of the Project beginning in approximately Year 19 through

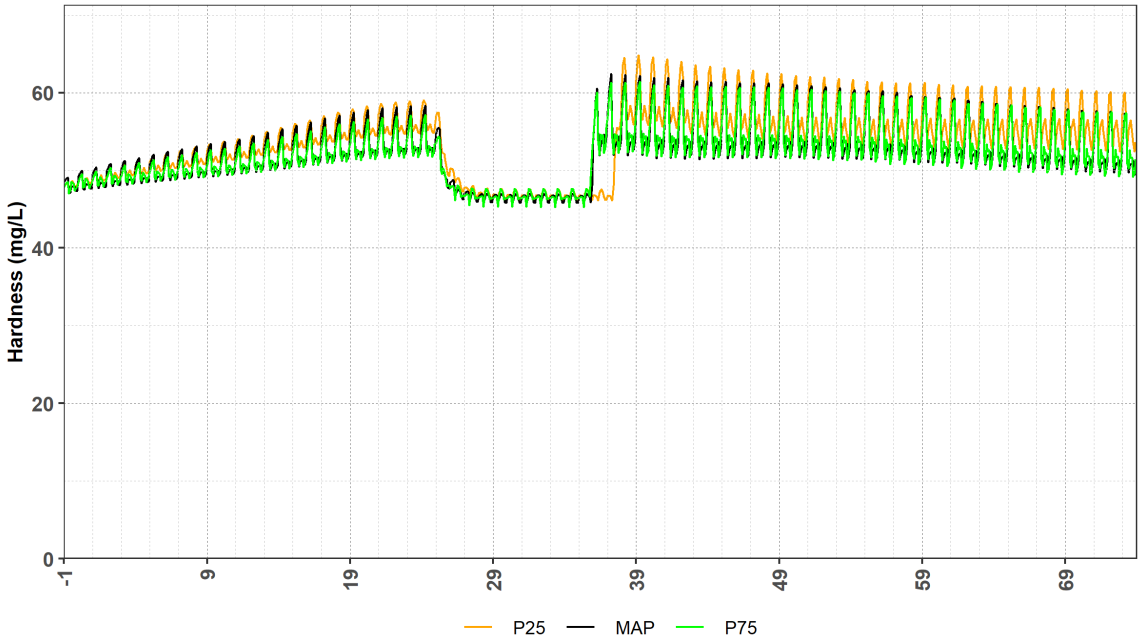
Year 24 (Figure 4-9). Project effects on total selenium do not persist above the CCME guideline during Closure when the Rose Pit is being flooded. Following flooding of the Rose Pit, seepage from reclaimed OSP is allowed to passively discharge to Pike Lake via diffuse flowpaths. Beginning in Post-closure (Year 36), Project effects on total selenium are consistently above the CCME guideline.

Figure 4-7: Time Series of Modelled Predictions of Total Cobalt for P25, MAP, and P75 Model Scenarios for Pike Lake



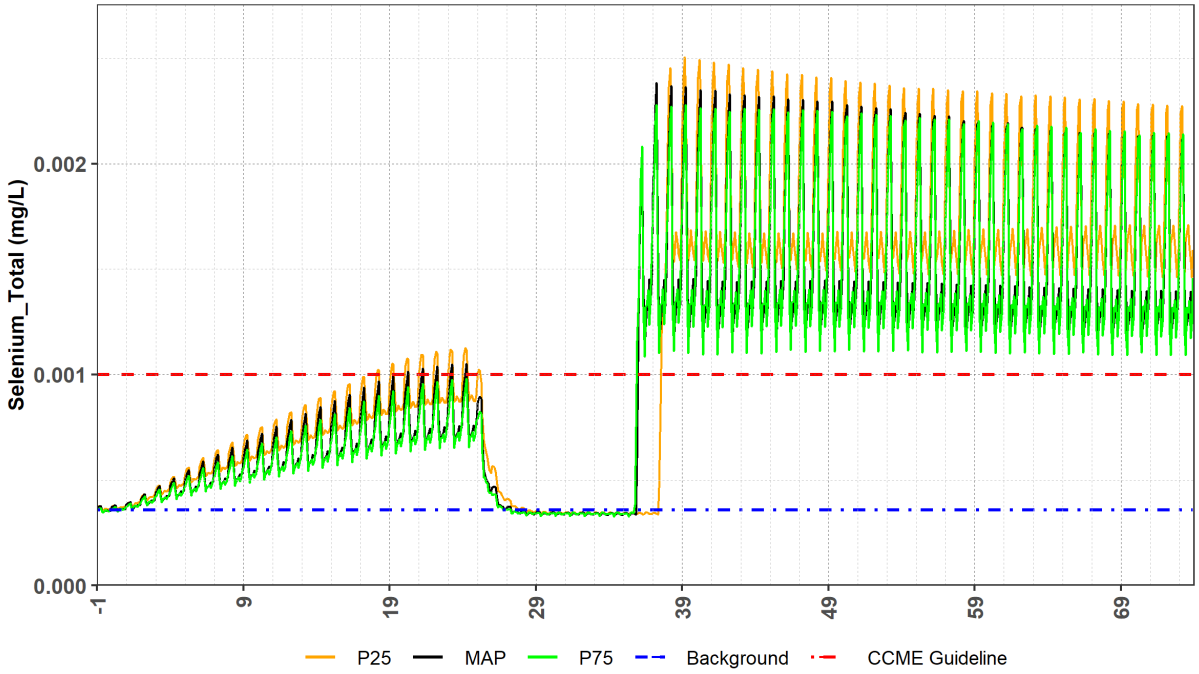
Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

Figure 4-8: Time Series of Modelled Predictions of Hardness for P25, MAP, and P75 Model Scenarios for Pike Lake



Notes: mg/L = milligrams per litre; MAP = mean annual precipitation.

Figure 4-9: Time Series of Modelled Predictions of Total Selenium for P25, MAP, and P75 Model Scenarios for Pike Lake



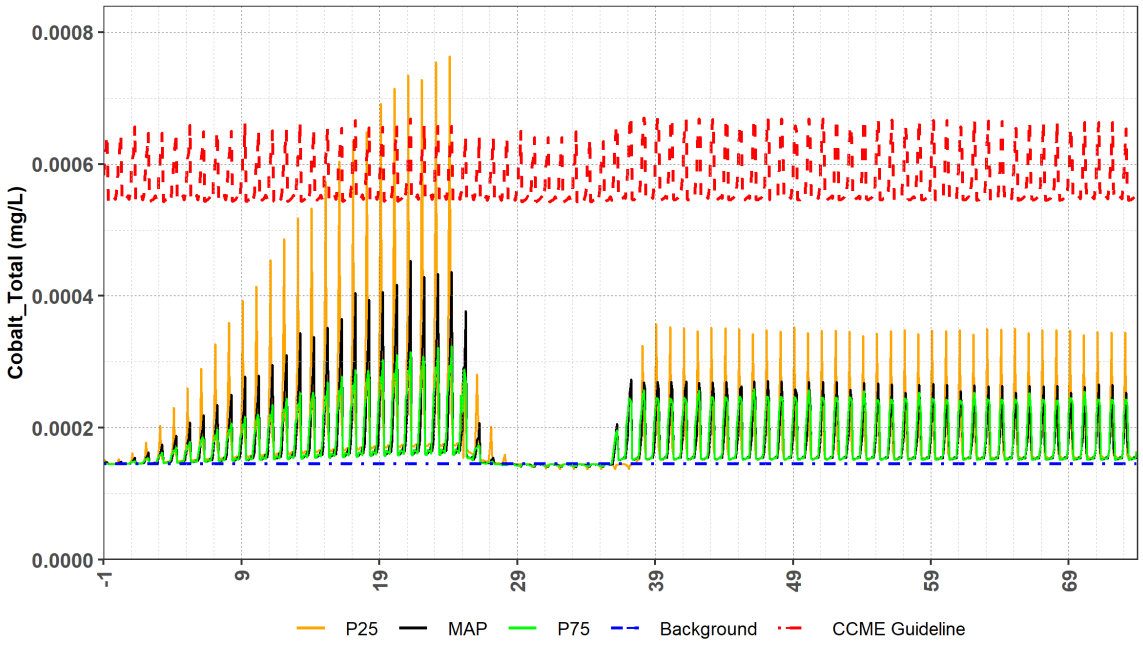
Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

4.2.4 Walsh River

Similar to Pike Lake, Project effects in Walsh River can be separated into the Operations phase and Post-closure period. During Operations, Project effects are limited to total cobalt due to water transfers from Duley Lake, as required to meet fish and fish habitat demands in Pike Lake. Project effects on cobalt in Walsh River occur late in Operations (+Year 19), are seasonally limited to P25 flow events, are reversible, and do not persist beyond operations (Figure 4-10). Project effects on hardness in Walsh River are included to inform the corresponding guidelines and associated effects assessment (Figure 4-11).

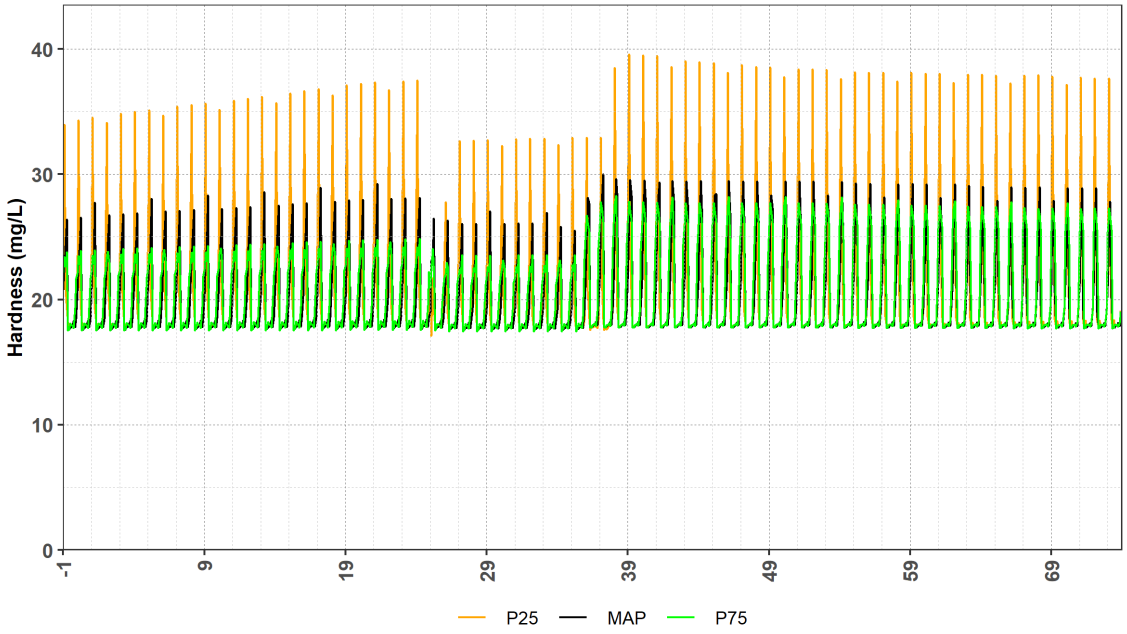
Project effects on total selenium in Walsh River occur during the Post-closure period (+Year 39) and are associated with passive discharge from the OSP (Figure 4-12). Project effects on selenium in Walsh River relative to the CCME guideline are seasonally limited to P25 flow events, are reversible, and infrequent.

Figure 4-10: Time Series of Modelled Predictions of Total Cobalt for P25, MAP, and P75 Model Scenarios for Walsh River



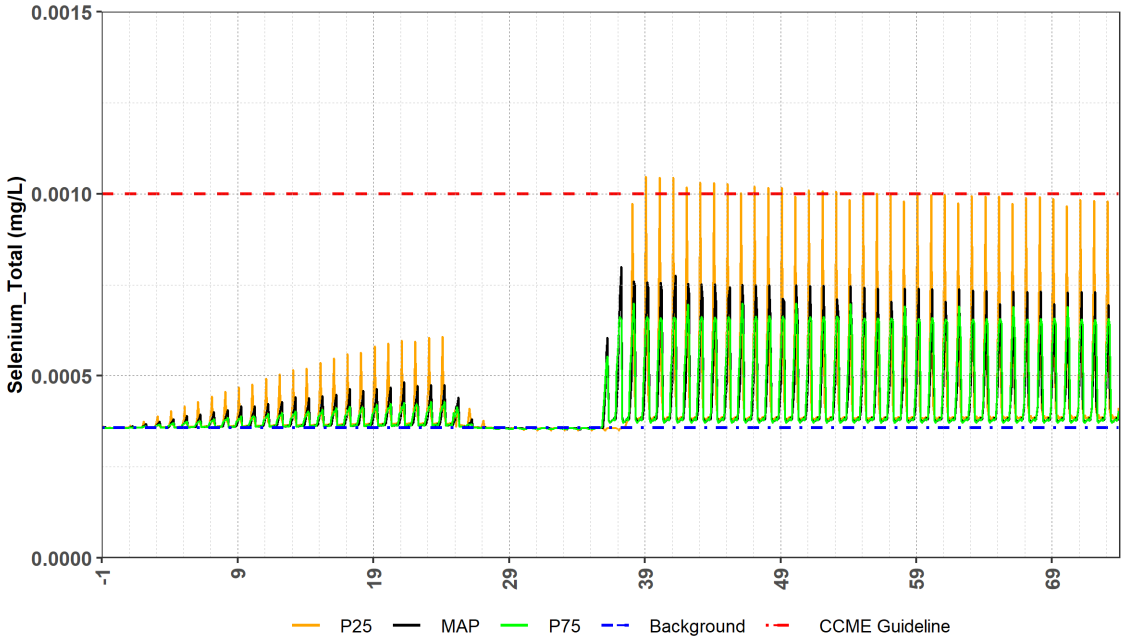
Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

Figure 4-11: Time Series of Modelled Predictions of Hardness for P25, MAP, and P75 Model Scenarios for Walsh River



Notes: mg/L = milligrams per litre; MAP = mean annual precipitation.

Figure 4-12: Time Series of Modelled Predictions of Total Selenium for P25, MAP, and P75 Model Scenarios for Walsh River

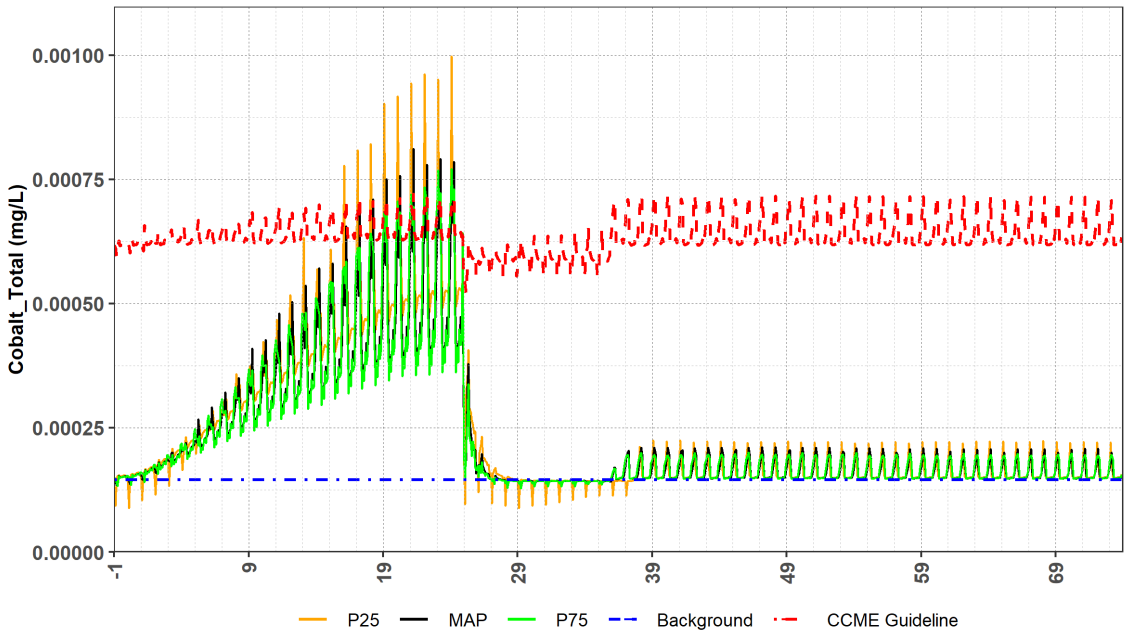


Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

4.2.5 Duley Lake Outlet

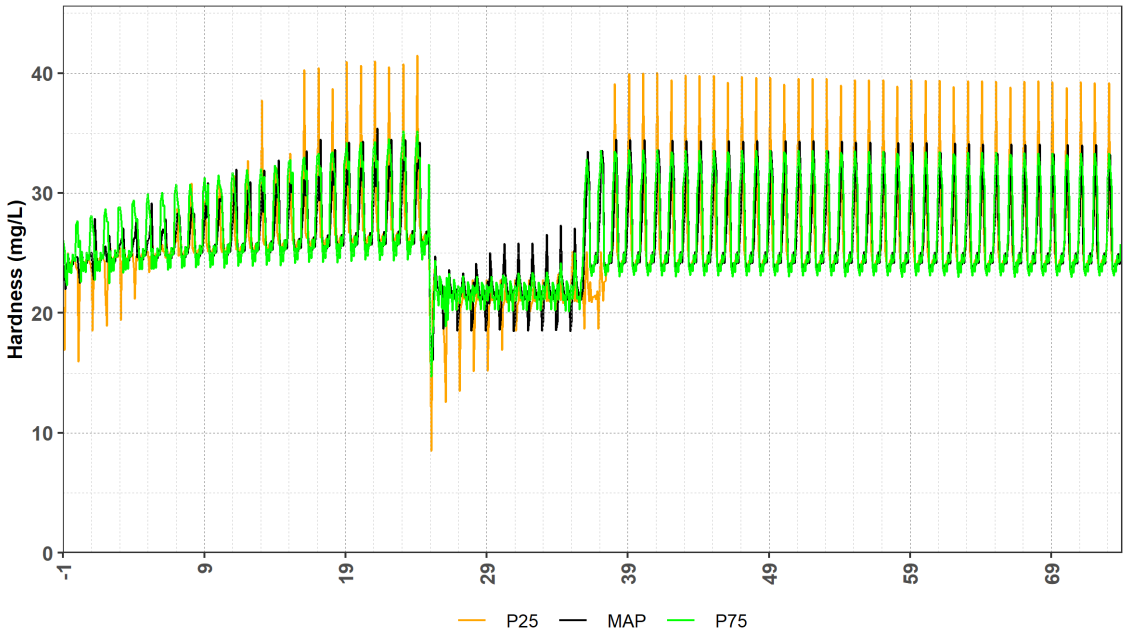
Duley Lake outlet simulations represent the combined discharge of Duley Lake and Walsh River and therefore represent the cumulative effect of the Project on existing conditions. Project effects on water quality at the Duley Lake outlet relevant to CCME guidelines are limited to total cobalt. Total cobalt is simulated to seasonally exceed CCME guidelines late in Operations (+Year 17) (Figure 4-13). Project effects on total cobalt are reversible and do not persist beyond operations. Project effects on hardness in Duley Lake are included to inform the corresponding guideline and associated effects assessment (Figure 4-14).

Figure 4-13: Time Series of Modelled Predictions of Total Cobalt for P25, MAP, and P75 Model Scenarios for the Duley Lake Outlet



Notes: mg/L = milligrams per litre; CCME = Canadian Council of Ministers of the Environment; MAP = mean annual precipitation.

Figure 4-14: Time Series of Modelled Predictions of Hardness for P25, MAP, and P75 Model Scenarios for the Duley Lake Outlet



Notes: mg/L = milligrams per litre; MAP = mean annual precipitation.

5. Model Assumptions and Limitations

5. Model Assumptions and Limitations

Key model uncertainties, conservatisms, and underlying assumptions are summarized in this section for water balance model and water quality model simulations.

Water balance model uncertainties, conservatisms, and underlying assumptions relevant to Project assessment are summarized here:

- The regional precipitation (CaPA) data were combined with the Wabush Lake A station data to produce a continuous, corrected precipitation time series, resolving concerns about the quality of recent records and the significant data gaps at the climate station.
- The water balance model incorporates groundwater inflow estimates to the pit, derived from a conservative scenario selected by AtkinsRéalis. This helps to ensure that the estimated volume of groundwater requiring dewatering and management is conservative. Additionally, the model conservatively represents groundwater seepage from Pike Lake, along with its potential impact on lake water levels and discharge.
- To mitigate the Project's impact on Pike Lake water levels and discharge due to groundwater seepage, the model assumes year-round water transfers from Duley Lake to Pike Lake, providing a conservative approach to managing these impacts.
- The water balance model assumes that seepage and potential groundwater losses from stockpiles and the TMF are reclaimed by water management infrastructure, including the TMF embankment and dam seepage collection system. Consequently, this assumption may overestimate water management infrastructure storage and conveyance requirements as it pertains to water balance and is therefore conservative.
- The water balance model assumes continuous basal seepage from the stockpiles throughout the year, including during the winter months, with water being directed to the respective collection ponds during Operations. This approach helps to ensure that the model conservatively accounts for the water volumes to be stored and managed year-round, including during the winter season.

Water quality model uncertainties, conservatisms, and underlying assumptions relevant to Project assessment are summarized here:

- Geochemical source terms for mine contact areas (pit high walls, stockpiles, tailings) were developed using median loading rates.

- Geochemical source terms were developed conservatively, noting that metal solubility and associated in situ attenuation mechanisms, as well as the effect of oxygen limitation on sulphide oxidation rates, were not considered.
- All PAG mine waste is managed within the MRS. Approximately 30% of mine waste within the MRS is classified as PAG or uncertain. MRS source terms assume PAG is well managed and blended to prevent locally acidic conditions. MRS source terms are coincidentally based on kinetic test data associated with neutral mine drainage (*e.g.*, non-acidic conditions).
- OSP source terms were developed from a single kinetic humidity cell test, which is based on a larger suite of analysis (Okane 2024b). Metal release rates from overburden remain uncertain.
- Studies are ongoing to address geochemical uncertainty and to inform PAG management, including additional geochemical characterization to improve the mine waste block model and to inform the development of a mine waste management program to address PAG and metal leaching uncertainty.
- All parameters are modelled conservatively (*e.g.*, no reactions along flowpaths), noting that metals associated with mine contact water recirculated through the process plant and TMF may be attenauted on reactive iron oxide surfaces.
- Project effects on TSS are not modelled and are managed through implementation of the sediment and erosion control plan and treatment in the Pit collection pond and water treatment facility at the process plant.
- Consistent with the water balance, the water quality model assumes no groundwater leakage or losses from mine facilities, including the stockpiles and TMF.
- Simulations of Project effects on Duley Lake conservatively exclude inflows from Walsh River, which have the potential to increase the dilution of Project discharges to Duley Lake by a factor of three to five times. Effluent discharge to Duley Lake is assumed to be well mixed within the lake due to seasonally driven mixing processes, the hydraulic retention time of the lake, and the modelled efficiency of the in-lake diffusor. Measured concentrations within the lake may vary on shorter time scales than modelled and may be lower than estimated along the lake shoreline and adjacent to lake inflows.
- Potential effects on Pike Lake during Operations are due to water transfers from Duley Lake, which could be offset by pulling water from sources upgradient of Duley Lake (*e.g.*, Mills Lake).

6. Closure

CHAMPION IRON

6. Closure

This technical data report was prepared by Lorax Environmental Services Ltd. in support of Kamistiatusset Iron Ore Project Environmental Assessment. Please contact the undersigned should you have any questions or require any clarification.

Sincerely,

LORAX ENVIRONMENTAL SERVICES LTD.

DISCLAIMER

This document has been provided by M.A. O'Kane Consultants Inc. (Okane) subject to the following limitations:

1. This document has been prepared for the client and for the particular purpose outlined in the Okane proposal and no responsibility is accepted for the use of this document, in whole or in part, in any other contexts or for any other purposes.
2. The scope and the period of operation of the Okane services are described in the Okane proposal and are subject to certain restrictions and limitations set out in the Okane proposal.
3. Okane did not perform a complete assessment of all possible conditions or circumstances that may exist at the site referred to in the Okane proposal. If a service is not expressly indicated, the client should not assume it has been provided. If a matter is not addressed, the client should not assume that any determination has been made by Okane in regards to that matter.
4. Variations in conditions may occur between investigatory locations, and there may be special conditions pertaining to the site which have not been revealed by the investigation, or information provided by the client or a third party and which have not therefore been taken into account in this document.
5. The passage of time will affect the information and assessment provided in this document. The opinions expressed in this document are based on information that existed at the time of the production of this document.
6. The investigations undertaken and services provided by Okane allowed Okane to form no more than an opinion of the actual conditions of the site at the time the site referred to in the Okane proposal was visited and the proposal developed and those investigations and services cannot be used to assess the effect of any subsequent changes in the conditions at the site, or its surroundings, or any subsequent changes in the relevant laws or regulations.
7. The assessments made in this document are based on the conditions indicated from published sources and the investigation and information provided. No warranty is included, either express or implied that the actual conditions will conform exactly to the assessments contained in this document.
8. Where data supplied by the client or third parties, including previous site investigation data, has been used, it has been assumed that the information is correct. No responsibility is accepted by Okane for the completeness or accuracy of the data supplied by the client or third parties.
9. This document is provided solely for use by the client and must be considered to be confidential information. The client agrees not to use, copy, disclose reproduce or make public this document, its contents, or the Okane proposal without the written consent of Okane.
10. Okane accepts no responsibility whatsoever to any party, other than the client, for the use of this document or the information or assessments contained in this document. Any use which a third party makes of this document or the information or assessments contained therein, or any reliance on or decisions made based on this document or the information or assessments contained therein, is the responsibility of that third party.
11. No section or element of this document may be removed from this document, extracted, reproduced, electronically stored or transmitted in any form without the prior written permission of Okane.

EXECUTIVE SUMMARY

Okane Consultants (Okane) was retained by Champion Iron Mine Ltd. (Champion) to develop source terms for mine storage facilities with Lorax Consultants (Lorax) for the water balance water quality model (WQWBM) that will be submitted as part of the Environmental Assessment (EA) stage of the Kamistiatusset Iron Ore Mine Project (Kami Project).

Source terms were developed for the planned Mine Rock Stockpile, Overburden Stockpile, pit surfaces, and Tailings Management Facility (TMF) for End of Mine (EOM) and Closure time steps. Source terms have been provided as fixed loading rates calculated from humidity cell test (HCT) data. Calculated loading rates were then scaled from laboratory to field scale and run through the geochemical model PHREEQC to consider solubility controls and charge balanced concentrations. Currently, Okane is running a parallel ongoing project to complete geochemical characterization of materials (Okane, 2024a; 2024b). The geochemical characterization work done to date analyzed results from Stantec (2013) in comparison with new geochemical analyses to validate use of the Stantec dataset to develop source terms provided herein. Additional details can be found in Okane (2024a).

Source terms for the Mine Rock Stockpile were calculated using the median loading rates from the last six weeks of HCT measurements from the different rock formations weighted based on expected tonnages for each formation. When analyzing the median results from all formations, loads represent HCT measurements that were not acidic; in this scenario it is assumed sufficient neutralization potential (NP) and mine rock blending maintain neutral pH conditions. The source terms provided in this report assume adequate blending of mine rock will be achieved, where Champion plans to ensure adequate blending of the Mine Rock Stockpile through several measures, including:

- Extracted mine rock will be crushed in-pit and transported to the Mine Rock Stockpile by conveyor, which will be used to distribute mine rock formations evenly to achieve blending and ensure sufficient NP exists to neutralize any acidity produced from potentially acid generating (PAG) rock.

- A PAG/metal leaching (ML) management program will be developed, which will include measures such as additional characterization of mine rock to update the PAG block model and routine quality assurance/quality control sampling to ensure sufficient NP is available in materials to neutralize any acidity generated from sulfide minerals.

Results of HCTs demonstrate that under acidic conditions, concentrations of certain metals (such as Cd, Co, Cu, Fe, Ni, and Zn) may increase relative to HCTs which remained neutral. Although sufficient NP exists in the material to maintain neutral conditions overall (Okane, 2024b), the feasibility of achieving adequate blending will be addressed in future studies, such as blended kinetic field bin tests and additional geochemical characterization as samples become available.

Similar to the Mine Rock Stockpile, a loading-based approach was used for the overburden and TMF dam embankment, which are planned to be constructed of overburden and non-potentially acid

generating (NPAG) materials, respectively. For the pit surfaces, acidic and non-acidic HCT results were grouped and used to represent PAG and NPAG materials, since it is assumed that acidic runoff along the pit surfaces have insufficient time for neutralization. Pit surface concentrations and loading rates were also developed using a loadings-based approach. Solubility controls were not considered due to the assumption that runoff water contact time with is short and insufficient to allow for precipitation of secondary minerals under equilibrium conditions.

This report describes data available, methods used to calculate loading rates provided for the WQWBM, and assumptions and limitations associated with these methods. Where possible, water quality has been compared to Bloom Lake Mine, which is only a few kilometers north-west of the Kami Project. While some general discussions of water quality are made within this report, no comparisons to regional water quality guidelines were made. Modeled water compared to water quality criteria and guidelines will be investigated by Lorax considering mixing of different waters under the water management plan for the Kami Project before discharge to the receiving environment.

1 INTRODUCTION

Okane Consultants (Okane) was retained by Champion Iron Mines Ltd. (Champion) to provide source terms for a water balance water quality model (WBWQM) currently being developed by Lorax Environmental Services Ltd. (Lorax) for the Kamistiatusset Iron Ore Mine Project (Kami Project). The Kami Project is located in Newfoundland and Labrador, Canada, near the Labrador-Quebec border, only a few kilometers south-east of the Bloom Lake Mine. The Kami Project will consist of an open pit (Rose Pit), the Mine Rock Stockpile, an overburden stockpile, a tailings management facility, and associated infrastructure. Okane and Lorax are developing a site-wide WBWQM for the Kami Project and are providing technical support during the Feasibility Study (FS) and Environmental Assessment (EA) process. Most of the source terms derived for the WQWBM come from previous geochemical characterization work completed for Alderon (WorleyParsons, 2014; Stantec, 2013). Okane is also involved in a parallel project to complete a geochemical characterization program (Okane, 2023; 2024a) which is referenced throughout this report to support use of data provided by Stantec (2013) and to fill in data gaps where applicable.

1.1 Project Objectives and Scope

The objectives of this report are to document the source terms and the methods used to develop them for the EA stage report, including assumptions, methods, and results, to be used for the WQWBM developed by Lorax with support from Okane. For the scope of this work, Okane developed and provided loading rates to be used in the WQWBM for the following facilities:

- Mine Rock Stockpile consisting of 840 Mt of crushed, blended mine rock from the major formations found in the Rose Deposit;
- Overburden Stockpile consisting of 125 Mt of overburden material;
- Pit surfaces where reactive surfaces of the Rose Pit are comprised of the lithologies mined in the above stockpiles; and a
- Tailings Management Facility (TMF), consisting of:
    - 406 Mt of coarse and fine tailings, and
    - 68.4 Mt of crushed non-potentially acid generating (NPAG) mine rock that makes up the tailings dam embankment.

At this stage of the model, source terms have generally been provided for two time steps:

1) An End of Mine (EOM) timestep, where materials were assumed to be fully wetted up and in steady state with respect to geochemical loads. This time step is assumed to begin at the end of the operations phase (year 25), assuming constant loading rates for source terms.

2) A Closure timestep, where covers have been placed on stockpiles as per the current closure plan, decreasing net percolation where applicable. Both flow and geochemistry are assumed to be steady state. At Closure, the pit will be allowed to fill with water – this is assumed to fill to the 568 m elevation (AtkinsRéalis, 2024).

2 BACKGROUND

Source terms discussed in this memorandum have been derived using existing geochemical data from previous geochemical characterization studies (WorleyParsons, 2014; Stantec, 2013) and preliminary results from the geochemical characterization program (Okane, 2024a; 2024b). Assumptions and limitations of the calculations and existing dataset are described herein. A loading based approach from HCT leachate measurements was taken to generate source terms for the EOM and Closure time steps, where scaling factors were applied to go from laboratory to field scale conditions. The geochemical model PHREEQC was then applied to calculated concentrations to consider solubility controls and charge balancing for final loading rates. Future refinements may be applied with additional studies and testing to address the assumptions and limitations noted in this report.

In addition to the source term development, Okane is leading an ongoing geochemical characterization program, which includes recommendations for additional sample testing including acid base accounting (ABA), four-acid elemental digest, shake flask extraction (SFE), and humidity cell testing (HCT) (Okane, 2024b). The geochemical characterization program will continue to provide understanding for mined materials to inform and update source terms (if necessary) at a later date.

2.1 Site Description

The Kami Project will extract iron oxide ores from the Rose Deposit, which is divided into the Rose North (RN) and Rose Central (RC) areas. According to the mine plan, mine rock will be excavated from the Rose Pit through blasting and crushing using an in-pit crusher, then moved via conveyor towards the Mine Rock Stockpile. Overburden will be shoveled and taken to the Overburden Stockpile. Tailings will be generated from the concentrator and deposited in the TMF (Figure 2.1).

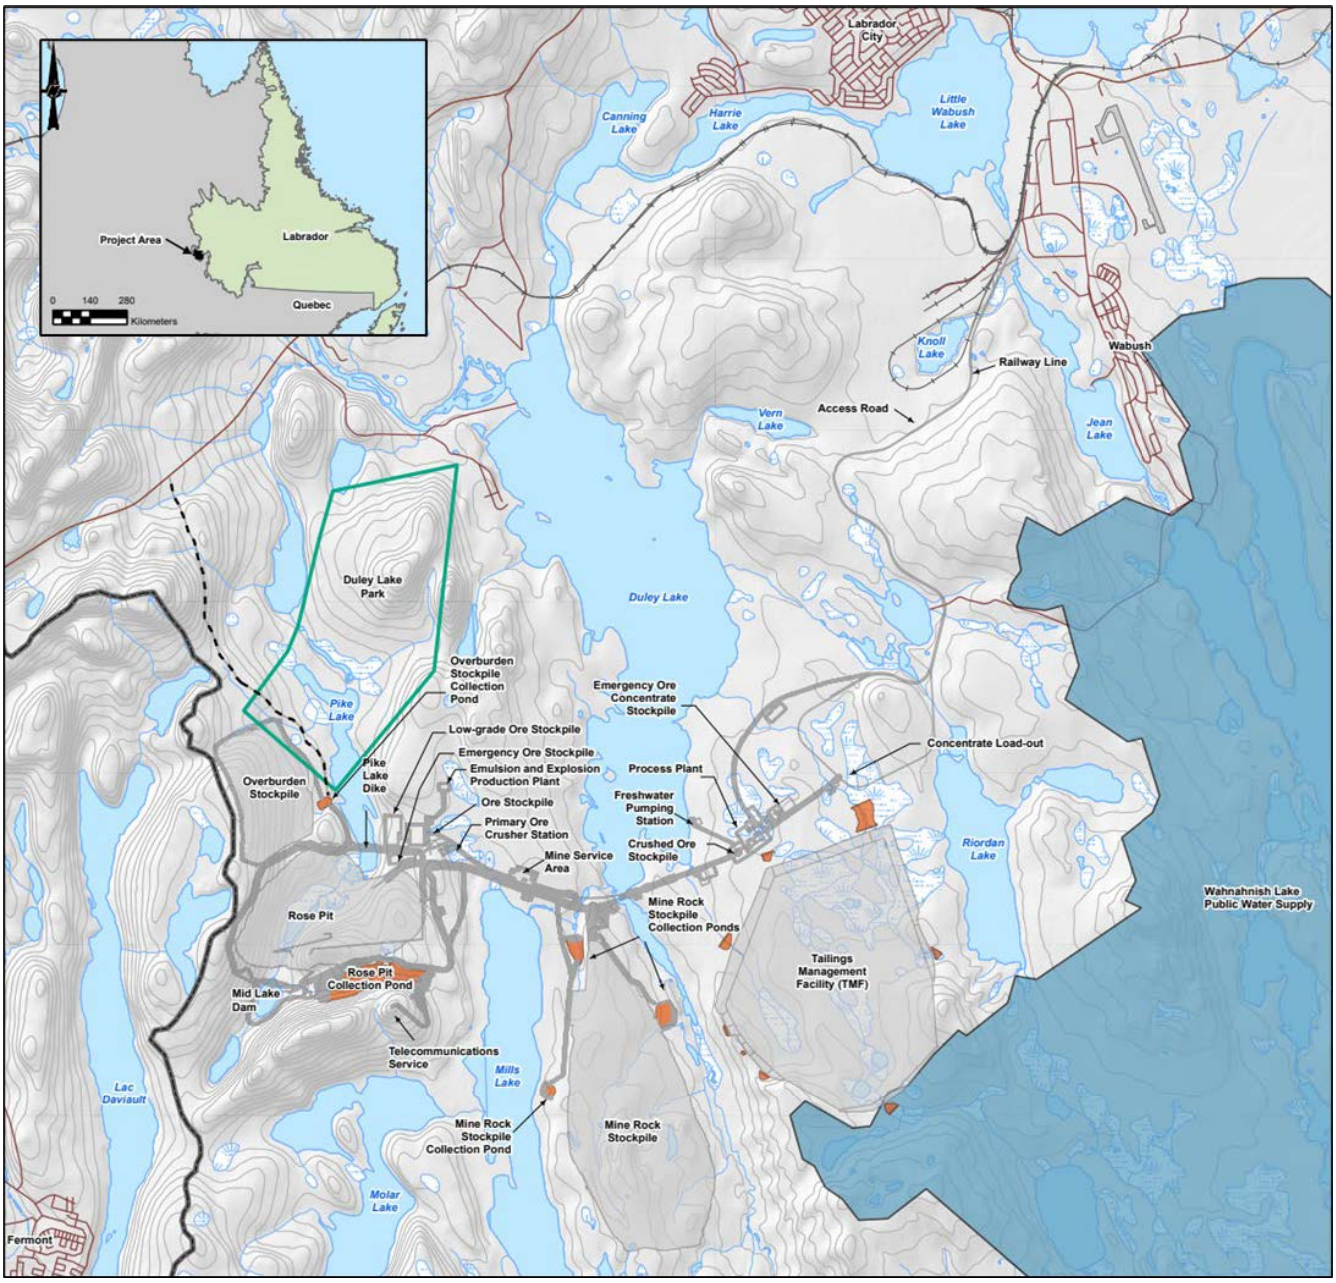

Figure 2.1: Layout and footprints of major mine material storage facilities for the Kami Project.

Modified site plan from WSP, 2025.

2.2 Material Characterization

2.2.1 Mine Rock and Overburden

Okane (2023) recommended expansion of the previous geochemical characterization work completed by Stantec (2013) and WorleyParsons (2014). The Kami Geochemical Characterization Phase II Report

(Okane, 2024b) includes laboratory results received to date from the latest geochemical characterization program. In the Phase I report (Okane, 2024a), comparison between the Stantec (2013) dataset and Okane (2023) datasets were completed using a variety of statistical tests. In general, there were no statistically significant differences between the datasets, with the following exceptions:

1) There were some statistical differences in the Sokoman Formation ABA (greater acid generation risk in the Okane dataset); however, this could be due to complex lithology previously noted in core logging work which identified interbedding of Sokoman and Menihek Formations (WorleyParsons, 2014). It was also observed that there were minor differences in the Wishart Formation (slightly more PAG) and Menihek Formation (slightly less PAG) samples.

2) Analysis of Variance (ANOVA) tests indicated statistically significant differences in NPAG samples, which could be related to differences in total neutralization potential (NP) methods used between the 2013 and 2023 datasets.

The generally good alignment between ABA and elemental digest results in these datasets to date supports the use of the Stantec (2013) samples for developing source terms for the WQWBM. A total of 705 samples have been analyzed for ABA from the Okane and Stantec datasets according to guidelines by Price (2009) for the total mine rock tonnages anticipated from the Kami Project.

Previous geochemical characterization work to date has segregated materials based on formation for the Mine Rock Stockpile and Overburden Stockpile. A summary of the mine rock unit, acid generation risk, and geology is provided in the list below (WorleyParsons, 2014; Okane, 2024a). In this report, NPAG is defined as having a neutralization potential ratio (NPR = NP/AP) greater than 2. Typically, materials with $2 < NPR \leq 1$ are classified as Uncertain; however, for material classification in this report, rock with $NPR \leq 2$ is assumed to be PAG.

1) The Denault Formation is classified as NPAG with very high NP and NPR values and mainly consists of dolomitic marble. Low metal leaching risk was associated with this unit.

2) The Katsao Formation is classified as uncertain and consists mainly of banded gneiss that includes potassium and plagioclase feldspars, various micas, and quartz. The Katsao Formation may be associated with exceedances for Cd, Co, Ni, and Se.

3) The Menihek Formation is classified as PAG, with the highest risk material coming from the graphitic mica schist lithology, though it also contains non-graphitic, fine mica schist and amphibole-biotite-garnet gneiss. The Menihek Formation demonstrates complex geology and includes banded lithologies and complex interbedding of the Sokoman and Menihek Formations. Low metal leaching potential was associated with the hornblende-biotite gneiss of the Menihek Formation, though mica schists may be associated with exceedances for Cd, Co, Cr, Cu, Ni, Se, Fe, Zn, and U.

4) The Sokoman Formation hosts the ore bodies as well as mine rock and is classified as NPAG. The Sokoman Formation that is considered mine rock in contact with the Menihek Formation includes an undefined mix of silicates and carbonates. Low metal leaching risk was generally associated with Sokoman units, with marginal exceedances of As from Sokoman quartz silicate iron formation samples and Se in overburden leachate.

5) The Wishart Formation is classified as NPAG and is dominated by granular quartzite and mica-quartz schist with disseminated calcite near the top. Low metal leaching risk was associated with this unit.

6) Overburden was classified as NPAG, with low risk of metal release. The overburden is mainly till, though topsoil and peat containing organic matter was highlighted in the few samples that were noted to contain some acid generating risk. Low metal leaching potential was associated with the overburden.

Updates to the block model were provided by Champion to develop a percentage breakdown for the final life of mine (LOM) mine rock volumes (Table 2.1). An estimated 68.4 Mt of NPAG rock will be used to construct the TMF dam embankment (Ghirian A. (WSP), *personal communication*, November 29, 2023), which is assumed to be equally divided between Sokoman and Wishart Formation mine rock in the generation of source terms.

Table 2.1: Tonnages of mine rock placed in storage facilities by formation.

Formation	Mine Rock Stockpile (t)	TSF Dam Embankment (Mine Rock) (t)	Overburden Stockpile (t)	Percentage of Mine Rock Stockpile	Percentage of Total Material from Rose Pit
Denault	5,007,164			0.6%	0.5%
Katsao	150,836,741			17.9%	14.5%
Menihek	229,137,610			27.3%	22.1%
Overburden			125,002,236	0%	12.0%
Sokoman	302,591,187	36,391,813		36.0%	32.7%
Wishart	152,746,823	36,391,813		18.2%	18.2%
Total	840,319,525	68,389,248	125,002,236		100%

Although only the Menihek Formation is classified as PAG, ABA results from the geochemical characterization study (Okane, 2024b) indicate that PAG rock is present in all mine rock units except for the Denault. In addition to the breakdown by mine rock formation in Table 2.1, ABA classification within Formation type was considered in the materials which will be discussed in Section 3. A summary of the ABA statistics (Table 2.2) and the weighted percent contribution of PAG (which includes PAG and Uncertain) and NAG materials into the Mine Rock Stockpile (Table 2.3) is summarized below for reference from the Geochemical Characterization Phase II Report (Okane, 2024b). The number of samples (702) analyzed in total were based on the Price (1997) guidelines which provide guidance for the number of

samples for preliminary static testing based on the total tonnage of mine rock. For additional details of sample selection, refer to Okane (2023; 2024b).

Table 2.2: Summary of ABA parameter statistics by formation.

Wishart	149	2.0%	16.2%
Total	702	31.4%	68.6%

To investigate the feasability of blending mine rock so that acidity may be neutralized by the NP available throughout different phases of the mine, Mineralis Services-Conseils Inc. (2024) was retained by Champion to develop an ABA block model. The ABA block model and the lithological block model are maintained by Champion, which were used to provide Okane with estimated tonnages over the life of mine and the median AP, NP, and NPR by rock formation. After removing the required tonnages of NPAG rock required for construction material, the formation weighted NPR was calculated for five year increments of the mine plan. Given the current extraction schedule and interpretation of the block model, it is expected that sufficient NP will be extracted throughout the different phases to neutralize AP within the pile and that the overall Mine Rock Stockpile will be classified as NPAG (with NPR values > 2) throughout its entire construction (Figure 2.2.). Champion noted that future iterations of these block models may change projected rock mass classifications with increased sample resolution.

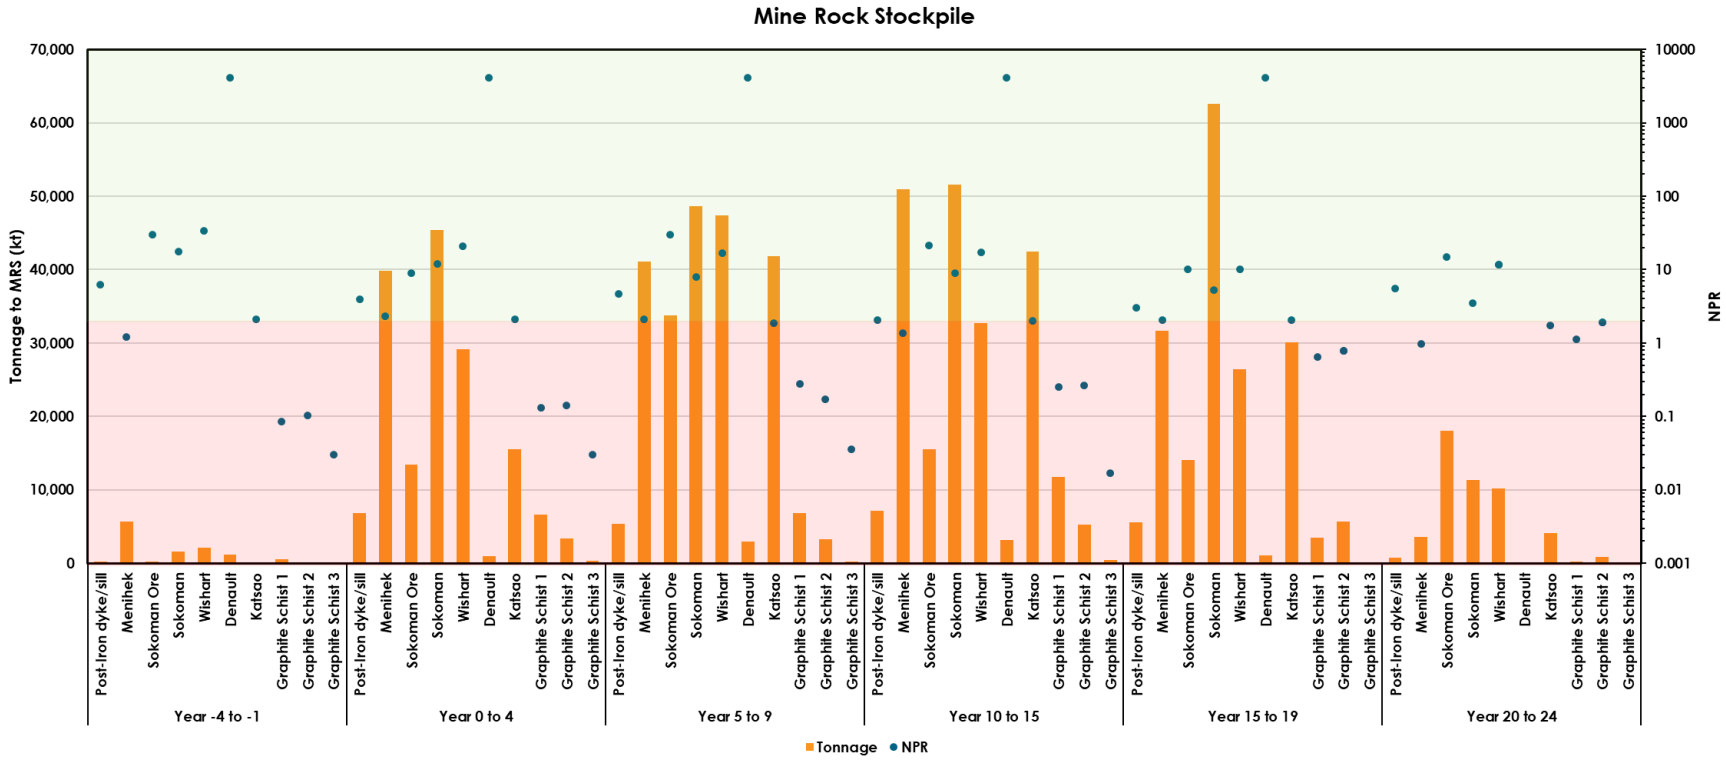

Figure 2.2: Mine Rock Stockpile tonnage placement and NPR by formation through five year increments.

Red indicates NPR values < 2, i.e. PAG, green indicates NPR > 2, i.e., NPAG.

2.2.2 *Tailings*

A tailings testing program was conducted in 2023 by Soutex Inc. (Soutex) for tailings from different composite samples and tailing streams. Tailings generated by ore processing at Kami will be subdivided into four streams (Bombard I. (Soutex), *personal communication*, November 17, 2023):

1) Cobber tails which are planned to make up 77% of the total tailings;
2) Finisher tails which are planned to make up 17% of the total tailings;
3) Gravity flotation tails which are planned to make up 6% of the total tailings; and
4) Magnetic flotation tails which are planned to make up less than 1% of the total tailings.

Three composite tailings samples were tested from the four different streams in the 2023 test program by Soutex:

1) A year 1 to 5 blend, representative of the ore blend in the first five years of mine life;
2) A Rose Central (RC) blend, where the majority of the tailings are from processing of the RC ore body; and
3) A Rose North (RN) blend, where the majority of the tailings are from processing of the RN ore body.

Samples were collected for ABA, whole rock analysis, trace metals, SFE, XRD, and water quality on supernatant samples as part of the geochemical characterization program (Okane, 2024b). Sample results were comparable to Stantec (2013); all samples were classified as NPAG with high NPR values and low risk of metal leaching. However, SFE and supernatant results found exceedances in NH_3 and F. Additional details can be found in the Geochemical Characterization Phase II Report (Okane, 2024b).

Kinetic testing is ongoing for tailings materials; however, stabilized loading rates from the kinetic test program were not available for the current WQWBM iteration. Stabilized loading rates from kinetic columns are expected to be representative of loading rates produced from the solid tailings materials after supernatant has been flushed from the initial pore volume. During operations, it is likely that the majority of water coming from the tailings material will be represented by the supernatant water quality. Therefore, supernatant samples taken from preliminary testing by Soutex were selected for the source terms at this time. These may not be representative of a steady-state closure time step, where it is expected that the water table will lower and supernatant may be flushed out of the tailings. However, this will be assessed within the WQWBM and may be reassessed in a later version of the model when additional kinetic data from the tailings columns becomes available.

3 METHODS FOR SOURCE TERM DEVELOPMENT

Source terms were developed using primarily existing geochemical characterization data completed by Stantec (2013) and preliminary geochemical characterization test work by Okane (2024b). For the current phase of the WQWBM, source terms were provided for two timesteps:

1) An EOM timestep, where all materials are placed and assumed to be fully wetted up and geochemically stable with respect to secondary mineral precipitation.

2) A Closure timestep, where covers have been placed on stockpiles as per the current closure plan. Both flow and geochemistry are assumed to be steady state. At Closure, the pit will be allowed to fill with water to 568 m elevation.

For steady state time steps, loadings were provided as fixed rates that were checked for charge balance and solubility controls using the geochemical model PHREEQC. Details regarding measured inputs, source term calculations, and geochemical modelling for solubility controls for each mine storage facility are described in this section.

3.1 Seepage Modelling

Seepage modelling work was completed by Lorax with support from Okane for the WQWBM. Steady-state flow rates were provided by Lorax for both the EOM and Closure timesteps to calculate concentrations for water quality from the source terms discussed below. For the Closure timestep, the cover system placed on the Mine Rock Stockpile is expected to decrease net percolation between 25 to 50% as per the International Network for Acid Prevention (INAP) Global Cover Guidance document (INAP, 2017). For additional details of the flow modelling, refer to the WQWBM report completed by Lorax.

3.2 Mine Rock and Overburden

3.2.1 Mine Rock Stockpile

Mine rock source terms for the Mine Rock Stockpile were derived from HCTs using a loading-based approach. Fourteen HCTs from Stantec (2013) and one HCT managed by Okane (2024d) were used to develop loading rates for the Mine Rock Stockpile. Humidity cell tests were operated between 15 to 50 weeks, where median loading rates were calculated from stabilized test results using the last six weeks of testing for the different formations. When values from HCTs were reported as less than the detection limit, the detection limit was used. Concentrations for selected parameters for the 15 HCTs used are shown in Figure 3.1.

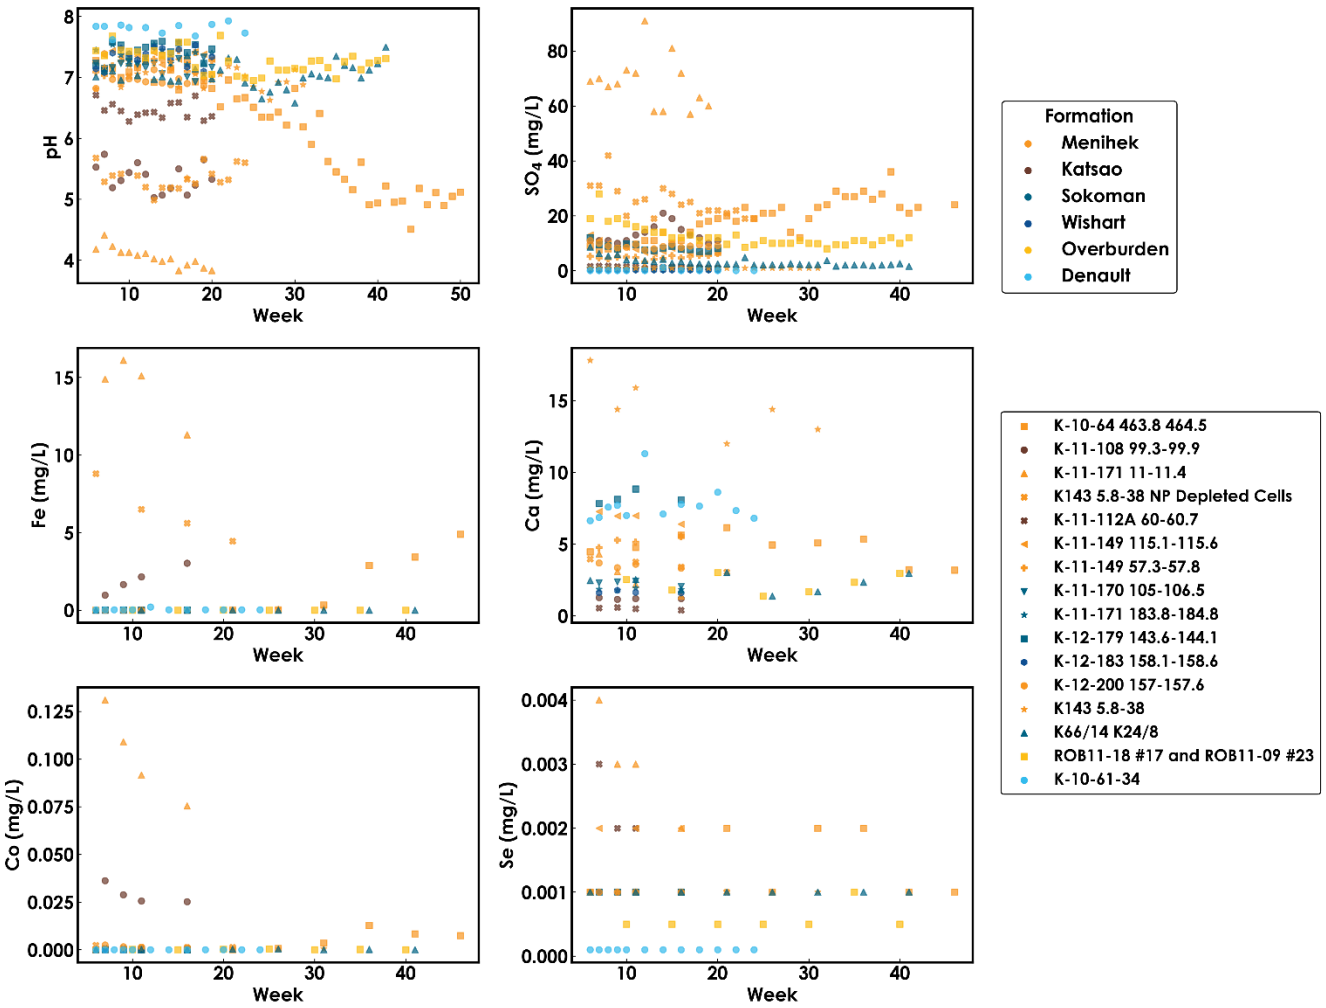

Figure 3.1: Humidity cell test results for selected parameters used for the generation of source terms.

For the Mine Rock Stockpile, a perfect blend of the different rock formations is assumed, where median loading rates from the last six weeks of HCT measurements from different rock formations were weighted together. No acidic HCTs were captured in the development of these source terms, as it is assumed sufficient NP and blending will maintain neutral pH conditions. Additional details of this scenario are described in Sections 4 and 4.5.

After HCT scale loading rates were derived, a total scale factor of 0.0025 was applied to scale from laboratory to field scale consisting of:

- A scale factor of 0.025 was applied using the Arrhenius equation to scale for temperature differences between the laboratory (25°C) and annual field temperatures at the Kami Project (-3°C), assuming an activation energy of 88,000 J/mol (Nicholson, et al. 1988);
- A scale factor of 0.2 was applied for grain size correction; and

- A channelization factor of 0.5.

The scaled, weighted source terms derived for the Mine Rock Stockpile were then applied to the 840 Mt of mine rock to generate annual loading rates. Concentrations were then calculated by dividing loads by annual seepage rates, which were then run through PHREEQC modelling for solubility controls (see Section 3.5).

3.2.2 *Overburden Stockpile*

The Overburden Stockpile is currently planned to be constructed of only overburden material. Source terms were developed similarly for the Mine Rock Stockpile, relying on one HCT from Stantec (2013) for overburden material to develop loading rates (Figure 3.1). This HCT is a blend of two overburden samples, ROB11-18 #17 and ROB11-09 #23. The sample ROB11-09 #23 used in this column is classified as PAG, with total S and sulfide contents which are higher than the 95th percentile values for all overburden samples tested (Table 2.2; Table 3.1). While blended with a high NP-containing sample (ROB11-18 #17), due to the association of metals (e.g., As, Cd, Co, Cu, Fe, Ni, Se, Zn) with sulfide mineral oxidation, the use of this single HCT to represent the entirety of the Overburden Stockpile may result in higher loading rates than is expected to be representative. Additional kinetic tests for overburden may be used in future model iterations to develop more representative loading rates.

Table 3.1: ABA for samples in overburden HCT to develop Overburden Stockpile loading rates.

Sample ID	AP (kg $CaCO_3$/t)	Modified Sobek NP (kg $CaCO_3$/t)	NNP (kg $CaCO_3$/t)	NPR	Paste pH	Total S (wt.%)	Sulfide-S (wt.%)	Total Inorganic C (wt.% CO_3)
ROB11-09 #23	28.13	0.7	-27.4	0.025	4.19	0.952	0.9	11.4
ROB11-18 #17	0.31	14	13.7	44.8	9.3	0.035	0.01*	0.536

* Detection limit value. Stantec 2013.

The same scaling factor of 0.0025 was applied for the Overburden Stockpile. Annual loading rates and concentrations were calculated and modelled using the same methods as the Mine Rock Stockpile.

3.2.3 *TMF Dam Embankment*

The TMF dam embankment is currently planned to be constructed using 68.3 Mt of NPAG rock (Figure 3.2), which was assumed to come from the Sokoman and Wishart Formations (Table 2.1). It is Okane's understanding that this material will not be crushed using the in-pit crusher and instead will be blasted and trucked for dam construction. To develop source terms for the TMF dam embankment, the same method for the NPAG rock (weighted blending by Formation and scaling factors) was applied for the

Mine Rock Stockpile to develop loading rates, but only using results from the Sokoman and Wishart HCTs. It was assumed the mine rock (Figure 3.2) will be composed of 50% Sokoman and 50% Wishart. The rockfill in Figure 3.2 is covered by a liner and not expected to contribute to the loadings coming from the TMF embankment.

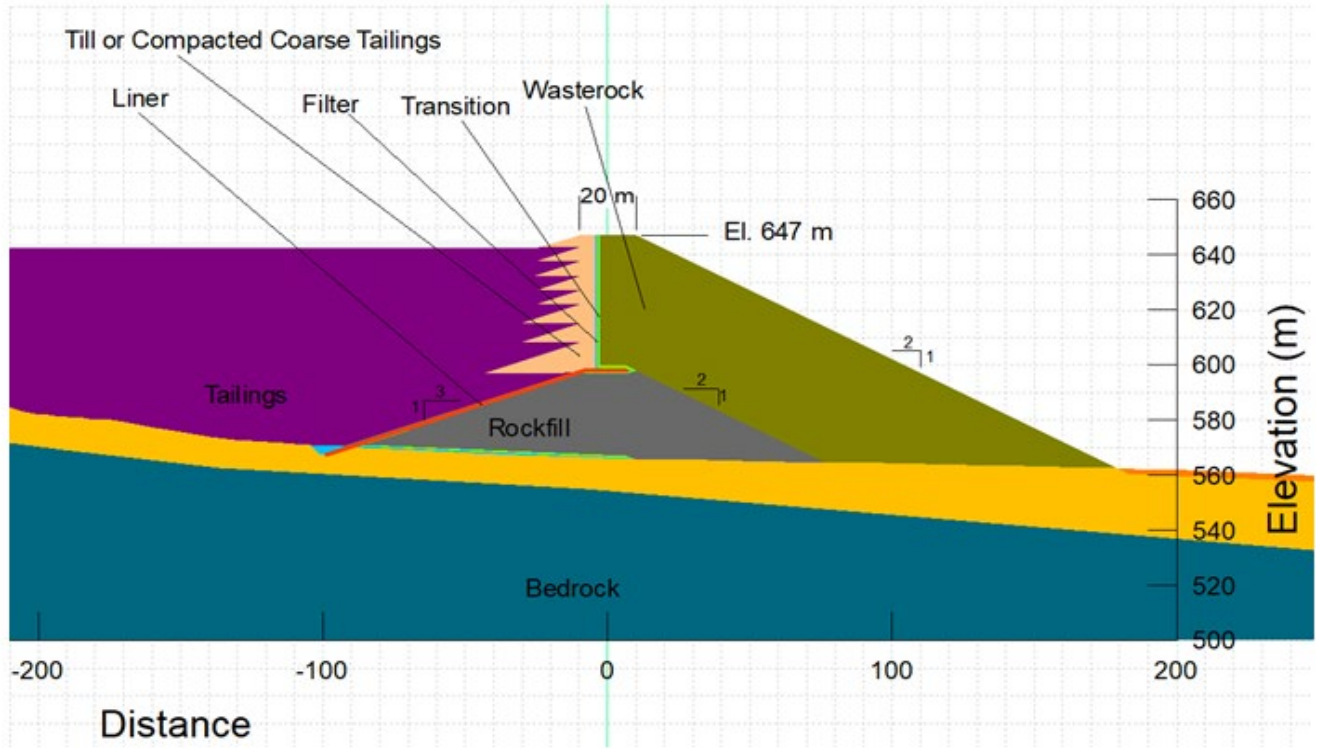

Figure 3.2: Tailings Management Facility cross-section showing dam constructed of mine rock.

Ghirian A. (WSP), *personal communication,* November 29, 2023.

3.3 Pit Surfaces

Loading rates for pit surfaces were calculated using a blend of HCT data, where weighting was based on the expected PAG, NPAG, and overburden exposed (measured as 3D surface areas of exposed rock by Champion from pit shells). For the exposed pit surfaces, it is assumed that acidic runoff along the pit surfaces has insufficient time for neutralization when contacting higher NP materials, therefore the loading rates are represented by acidic and non-acidic loading rates for mine rock. For acidic loading rates, four HCTs that went acidic (pH < 6.5) were grouped together to represent the exposed PAG rock loading rates. The remaining mine rock HCTs were used to calculate the NPAG loading rates, which were weighted by formation. The overburden loading rates at the HCT scale were the same as those used for the Overburden Stockpile. Since the exposed rock portions are expected to change over time as the pit becomes larger and deeper, weighted percentages of rock type and overburden were calculated using total exposed 3D pit surface area (including walls and benches) from Rose Pit in five year increments (Table 3.2) provided by Champion.

Table 3.2: Surface areas and weighting of formations in Rose Pit .

Formation	Year 0	Year 5	Year 10	Year 15	Year 20	Year 25 (EOM)	Closure
Denault	17,447	17,447	53,189	70,586	75,670	75,621	1,160
Katsao	11,287	423,564	600,873	667,002	753,615	768,713	121,654
Menihek	161,502	503,708	594,130	562,681	605,746	617,517	68,481
Sokoman	428,697	1,590,428	1,769,406	1,965,597	1,945,050	2,191,578	278,894
Wishart	277,814	376,225	433,853	483,640	540,654	590,184	24,596
Overburden	531,599	531,468	328,505	329,047	328,453	329,255	196,350
Total	1,428,346	3,442,840	3,779,955	4,078,553	4,249,188	4,572,869	691,135

To scale these from laboratory to field scale rates, a total scale factor of 0.0038 was applied considering the following:

- A scale factor of 0.025 was applied using the Arrhenius equation to scale for temperature differences between the laboratory (25°C) and annual field temperatures at the Kami Project (-3°C), assuming an activation energy of 88,000 J/mol (Nicholson et al. 1988).
- A scale factor of 0.2 was applied for grain size correction.
- A channelization factor of 0.75 was applied.

The calculation of pit surface loading rates is challenging in such early stages of the project without site-specific data to support loading rates, due to large ranges in the literature of reactive pit surface area (Kempton & Atkins, 2009), as well as uncertainties in pit wall integrity which may lead to formation of rubble zones alone the benches of the pile. To estimate pit surface concentrations for Kami without site-specific measurements, comparisons were made to measured concentrations at the Bloom Lake Mine, which is located 7 km north-west from the planned Kami site. Runoff flow rates were used to calculate concentrations of solutes in pit water collection ponds, which were compared to measured pit surface concentrations collected from the Bloom West Pit (FBW) used in the Bloom Lake water quality water balance modelling work (Okane, 2024c). Specifically, Bloom Lake pit water quality data was used to estimate the reactive pit surface depth to calculate the "reactive tonnage" of pit surfaces contributing solute load, which was considered a calibration factor for the development of pit surfaces source terms. A reactive depth of 3.5 m for the Bloom West Pit was selected which produced estimated concentrations and comparable loading rates for many parameters of interest within range of the Bloom Lake measured pit waters. A uniform reactive depth of 3.5 m was then applied to the exposed Rose Pit walls and benches. This reactive depth and tonnage considers fractures into the wall as well as the presence of rubble zones that are expected to accumulate along the pit benches. While it is likely that there are differences in the reactive depths for the walls and benches (rather than a uniform depth) from factors like the build up of rubble occurring along the benches and cracks in walls compared to more

compacted and solid benches, due to the calibration method at this stage, no differentiation between wall and bench reactivity was made. Distinction between walls and benches may be made as part of future model iterations if updates are made to improve resolution in walls compared to benches in the Bloom Lake pit model and/or when field data at Kami becomes available.

An assumed rock density of 2.5 t/m^3 was used, yielding 39.6 Mt of reactive pit surfaces (approximately 4.3% of the Mine Rock Stockpile tonnage). The EOM loading rates were composed of 70% NPAG rock, 24% PAG rock, and 6% overburden, based on the lithologies (Table 3.2) and ABA results (Okane, 2024b) exposed at that time step. In the Closure timestep, water is assumed to have filled up to 568 m elevation. This leaves less pit surfaces exposed in different proportions. In Closure, it is assumed that 31% NPAG, 11% PAG, and 58% overburden is exposed, with the same surface thickness and density during EOM. These proportions of source terms were applied to a resulting 6.0 Mt of reactive pit surfaces (approximately 0.66% of the Mine Rock Stockpile tonnage).

3.4 Tailings

Constant concentrations of supernatant were used for the tailings source terms. It is expected that supernatant will represent the water quality leaving the tailings during operations and the EOM period. At a certain point, supernatant will likely be flushed from the pores and tailings water will become reflective of water in contact with solid tailings. This is difficult to capture at this point without kinetic data of the tailings for a single fixed timestep. For this reason, Okane has also provided supernatant concentrations for the Closure time step; however, this may need to be revised after discussion of the WQWBM results with Lorax and when kinetic column test results become available.

The most recent process flow diagram for the tailings is provided for reference in Appendix A. In order to achieve representative supernatant samples from the cobber, finisher, and gravity flotation tailings streams, supernatant was made using dried tailings from the High RN composite sample and Long Lake water collected near the Kami site from the proportions outlined by Soutex (Appendix A). The High RN composite sample was selected due to material availability. This High RN supernatant sample was made by weighing out dried samples composited by Okane at the Saskatoon laboratory in the representative proportions and mixing the tailings materials with Long Lake water collected in June 2024 until a well mixed, muddy water was generated. The full suite of laboratory analyses on these water/supernatant samples is provided by Okane (2024b). Two samples were taken from this water, labeled High RN Blend and High RN Blend-Dup. An average was taken of these samples for the source terms.

3.5 Geochemical Modelling

To consider solubility controls that could limit the concentrations of some species (such as Al, Fe, and SO_4) and influence pH and acidity, equilibrium phase modelling using PHREEQC was completed for the following source terms using concentrations from the calculation methods above:

- Mine Rock Stockpile;
- Overburden Stockpile; and
- TMF dam embankment

Minerals allowed to precipitate in the geochemical models were barite ($BaSO_4$), calcite ($CaCO_3$), $Fe(OH)_3$, gibbsite ($Al(OH)_3$), and gypsum ($CaSO_4$:$2H_2O$), which were selected based on minerals that had a saturation index (SI) > 0 in initial PHREEQC equilibrium modelling and professional experience. Additionally, CO_2 was assumed to off gas from these facilities at atmospheric levels (assumed here around 400 ppm). The Lawrence Livermore National Laboratory (LLNL) database (Parkhurst and Appelo, 2013) was used for all equilibrium phase modelling. It was necessary to correct the solutions for charge balance as some major anions from Stantec (2013) were either not analyzed or not all reported. Charge balance was completed in PHREEQC using HCO_3^- for all materials, with the exception of the overburden stockpile, which SO_4 was used for the EOM time step. To check the charge balance on the overburden in Closure, a dilution calculation was completed and charge balance error was found to be less than 5% after running the solution in PHREEQC.

Pit surface runoff was not modelled for solubility controls. Conceptually, the water quality from the pit surfaces source term represents rainwater or snowmelt runoff along exposed pit surface areas which was assumed to not have sufficient time for secondary mineral precipitation to occur. Tailings supernatant was also not run for solubility controls, since the sampled water used in this iteration of source terms was supplied as fixed concentrations and considered representative of supernatant expected at the field scale.

Once equilibrium phase modelling was completed, total acidity was calculated by calculating the Lewis acidity from considered metals (Fe^{3+}, Fe^{2+}, Al^{3+}, Mn^{2+}, Cu^{+}, Cu^{2+}, Pb^{2+}, Zn^{2+}, As^{3+}, Ni^{2+}, Co^{2+}, Cr^{3+}, Cd^{2+}, Se^{4+}, Ag^{+}, Sb^{3+}, Bi^{3+}) plus the contribution from pH. After charge balancing, equilibrium modelling, and acidity calculations, the resulting concentrations were multiplied by seepage volumes to convert back into long-term Mine Rock Stockpile annual loads.

3.6 Nitrogen Source Terms

To account for the residual N from blasting in the mine rock, N source terms were derived based on the methods presented by Ferguson and Leask (1988). As part of a parallel project with Champion, Okane worked on a water balance water quality model for the Bloom Lake Mine (Okane, 2024c). To calibrate the N source terms for Kami, N loads were first calculated at the Bloom Lake Mine (including residual N remaining on the rock surface after blasting, flow rates used in the water quality/water balance model, and proportion of N reporting to pit surfaces and mine rock) using the Ferguson and Leask method (Equation 1), then applied to Kami stockpile tonnages. Results from the Bloom Lake Mine N loading calibration are provided in Appendix D.

As conditions are assumed to be wet, a 100% emulsion product will be used at Kami. The emulsion product (Fortis™ Extra) is composed of 70 to 85% ammonium nitrate, 3 to 7% petroleum, and 0.05 to 1% sodium nitrite (Dorval A. (G Mining), *personal communication*, August 1, 2023; Orica, 2019). Since 100% emulsion is used, the equation by Ferguson and Leask (1988) for mines using greater than 20% emulsion can be simplified here to:

$$N_{invetory} = 1.5\% \times \mathrm{R}_{Em} \times \mathrm{P}_N \times \mathrm{M} \qquad \text{(Equation 1)}$$

Where,

$N_{inventory}$ = Total residual N from explosives (kg);

R_{Em} = the powder factor or explosive application rate for emulsion (0.34 kg/t for mine rock and 0.4 kg/t for ore) (Dorval A. (G Mining), *personal communication*, August 1, 2023);

P_N = mass proportion of nitrogen, assumed here to be 0.3 (using the values of 85% ammonium nitrate and 1% sodium nitrite in emulsion composition); and

M = tonnage of mined material (mined rock) (t).

Tonnages of mined material (M in Equation 1) deposited at Kami over time used in calculations are provided below (Table 3.3). It is noted that a 1.5% N loss term was used rather than 5.1% suggested for emulsion by Ferguson and Leask (1988) after calibration at Bloom Lake (Appendix D). It is assumed that blasting practices have improved with respect to N loss in the last few decades; furthermore, it is noted by Ferguson and Leask (1988) that values were calibrated based on blasting practices in the Elk Valley (British Columbia), which may not be suitable for other sites. The decreased N loss term from the Bloom Lake calibration potentially also reflects how some N could be lost to unrecoverable seepage and groundwater. Similar for the planned blasting at Kami, Bloom Lake used 100% slurry and assumes holes are wet, with powder factors for mine rock of approximately 0.45 kg/t (higher than at Kami) and 0.4 kg/t for ore. Additional details for the Bloom Lake calibration are provided in Appendix D.

The $N_{inventory}$ is updated annually as more mine rock is placed. The total N dissolved each year is a function of the $N_{inventory}$ multiplied by leaching efficiency, assumed to be 90% based on work by Mahmood et al. (2017). The dissolved N is then converted to a concentration by dividing by the total Mine Rock Stockpile porewater estimated in storage, which is a function of the volume of rock multiplied by the volumetric water content (Equation 2).

$$N\ Concentration\ \left(\frac{mg}{L}\right) = \frac{N_{inventory}\ (mg) \times LE}{\frac{(V_R \times VWC)}{1000}} \qquad \text{(Equation 2)}$$

Where,

V_R = volume of rock (m^3);

VWC = volumetric water content; and

LE = leaching efficiency of 90%.

Some of this N is removed annually in seepage (calculated as the concentration of nitrogen multiplied by the seepage volume), which is used to update the annual inventory of nitrogen remaining in the Mine Rock Stockpile.

Table 3.3: Planned mine material tonnages deposited into storage facilities over mine life.

Mine Year	Total Mine Rock (t)[1]	Mined Ore (t)[1]	Mine Rock Stockpile (t)[1]	TMF Embankment Volumes (t)[2]

[1]Groleau M. (Champion), *personal communication*, October 9, 2024. [2]Equally divided from values provided over 3 year periods by Ghirian A. (WSP), *personal communication,* November 29, 2023.

Nitrogen is highly soluble and will be flushed at a rate dependent on site-specific conditions and contact with infiltrating water. Based on the water quality model results at Bloom Lake, it was assumed that 15% of the total blast residual N residual remains as a pit surface area source term (calculated using the ore tonnage and the mine rock tonnages in Table 3.3), while the remaining 85% of blast residual reports to the mine rock (i.e., the Mine Rock Stockpile or TMF Embankment). Seasonality effects of N release due to wet and dry seasons were not accounted for at this stage in the model.

Once calculated, N species were distributed amongst total N using data from mine rock seepage measured at Bloom Lake (Appendix D). Calculated total N concentrations were distributed across three N-species in the following proportions for the mine rock:

- 99.65% assumed as NO_3;
- 0.3% assumed as NH_3; and
- 0.05% assumed as NO_2.

And the following proportions for the pit surfaces:

- 70.5% assumed as NO_3;
- 28.5% assumed as NH_3; and
- 1.0% assumed as NO_2.

It is assumed that a higher portion of NH_3 is observed in pit water relative to seepage due to the fact that pit water runs off the exposed surfaces and then enters a pooled reservoir, where there is less time for nitrification to occur (converting NH_3 to NO_3) compared to seepage moving through the Mine Rock Stockpile. The proportion of these nitrogen species may vary from these estimates depending on redox conditions in the Mine Rock Stockpile and pit water collection areas. Unlike other source terms in this report, N species were provided on an annual basis rather than for EOM or Closure timesteps only due to the changes in concentrations expected as more rock is placed and N from blasting residue is leached from the rock.

Overburden is planned to be shoveled (not blasted) and transported by truck to the Overburden Stockpile (Champion, 2023). As N species were not tested in the HCT leachate for overburden or mine rock, no natural sources of N were considered at this time. When N is low, detection limit concentrations were used to generate loadings (i.e., 0.005 mg/L for NO_3, 0.003 mg/L for NO_2, and 0.005 mg/L for NH_3).

4 SOURCE TERM RESULTS

Source terms as loading rates were provided to Lorax where possible for use in the WQWBM, with calculated concentrations used for data checks and to calculate solubility controls in PHREEQC. Fixed concentrations were provided for tailings supernatant source terms, where limitations existed for data availability (identified in the previous section). No comparisons to regional water quality guidelines were made in this report, as this will be investigated in the WQWBM by Lorax considering mixing of different source waters under the water management plan for the Kami Project. All source term loading rates and concentrations are provided for N species in Appendix C and other parameters in Appendix E. A summary figure showing relative concentrations for all constituents between different source terms is shown for EOM (Figure 4.1) and Closure (Figure 4.2) and loading rates are shown for EOM (Figure 4.3) and Closure (Figure 4.4).

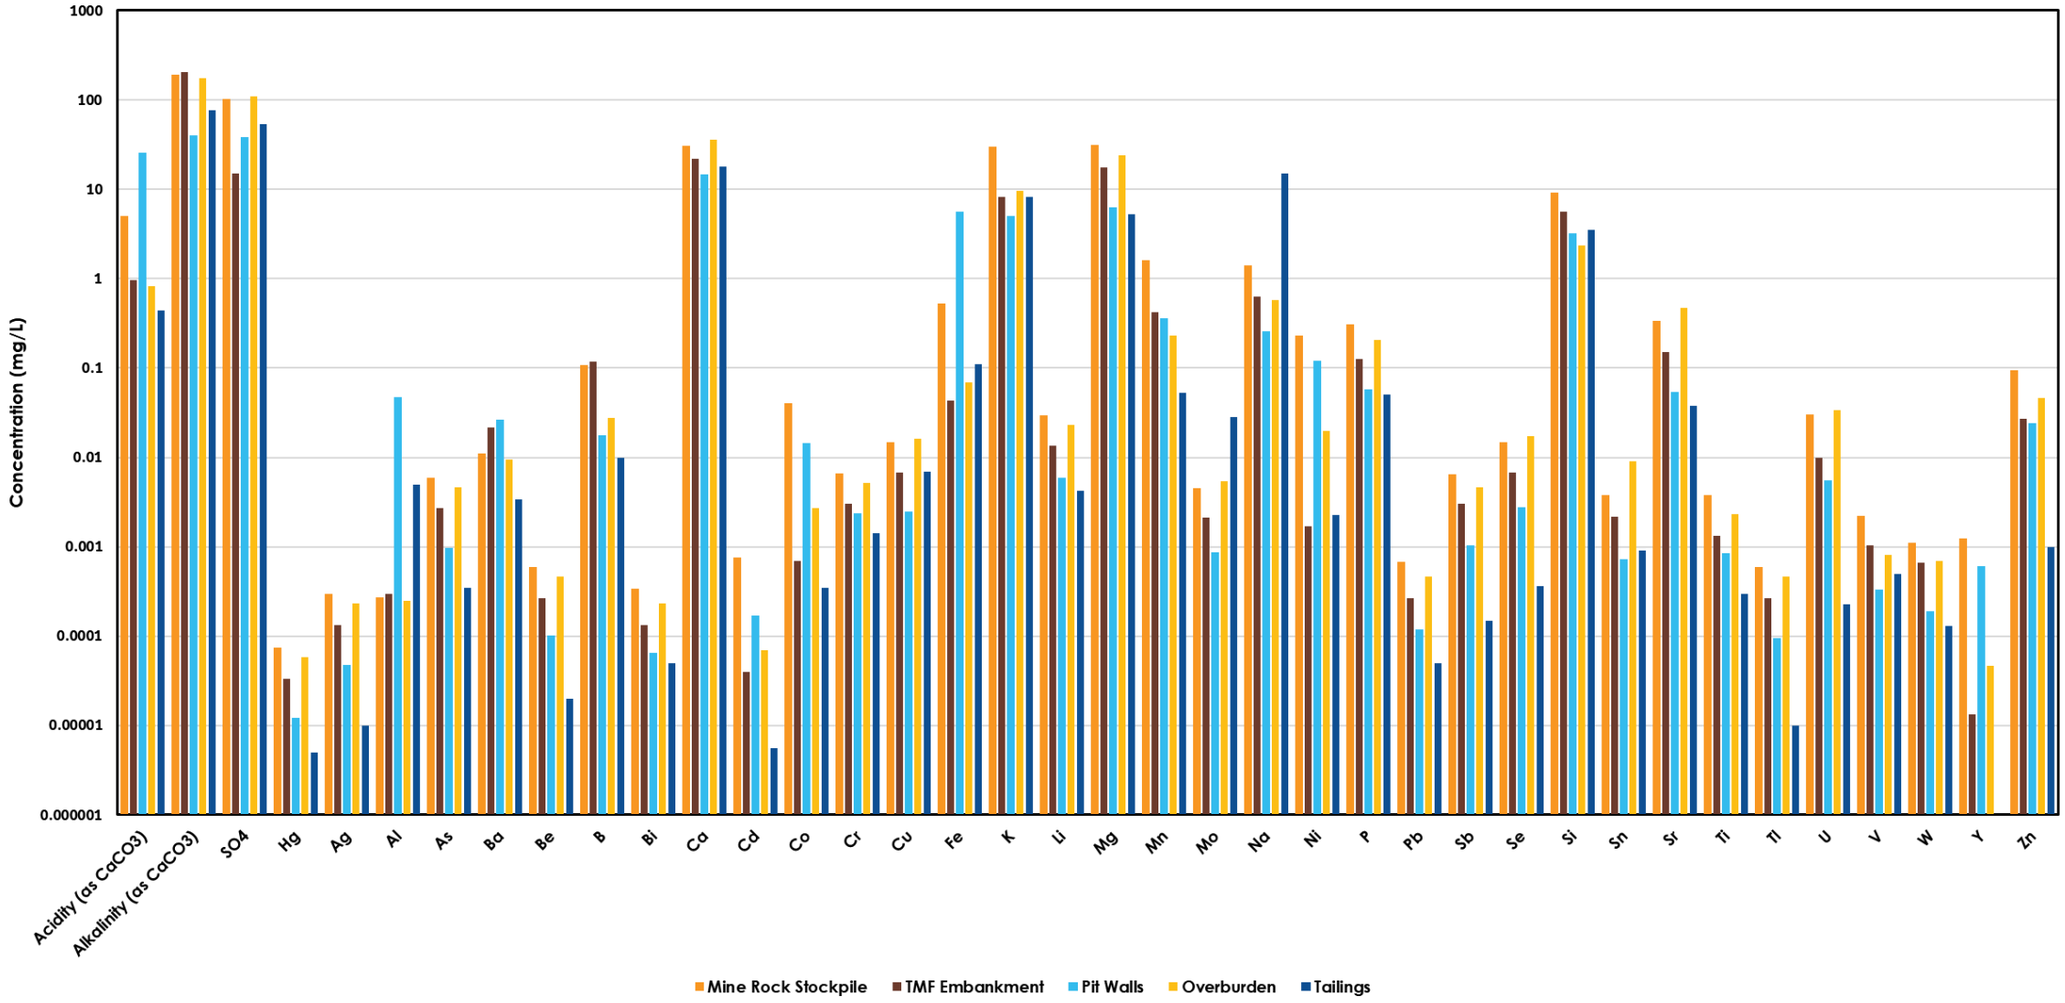

Figure 4.1: Concentrations at EOM for all constituents for source terms compared.

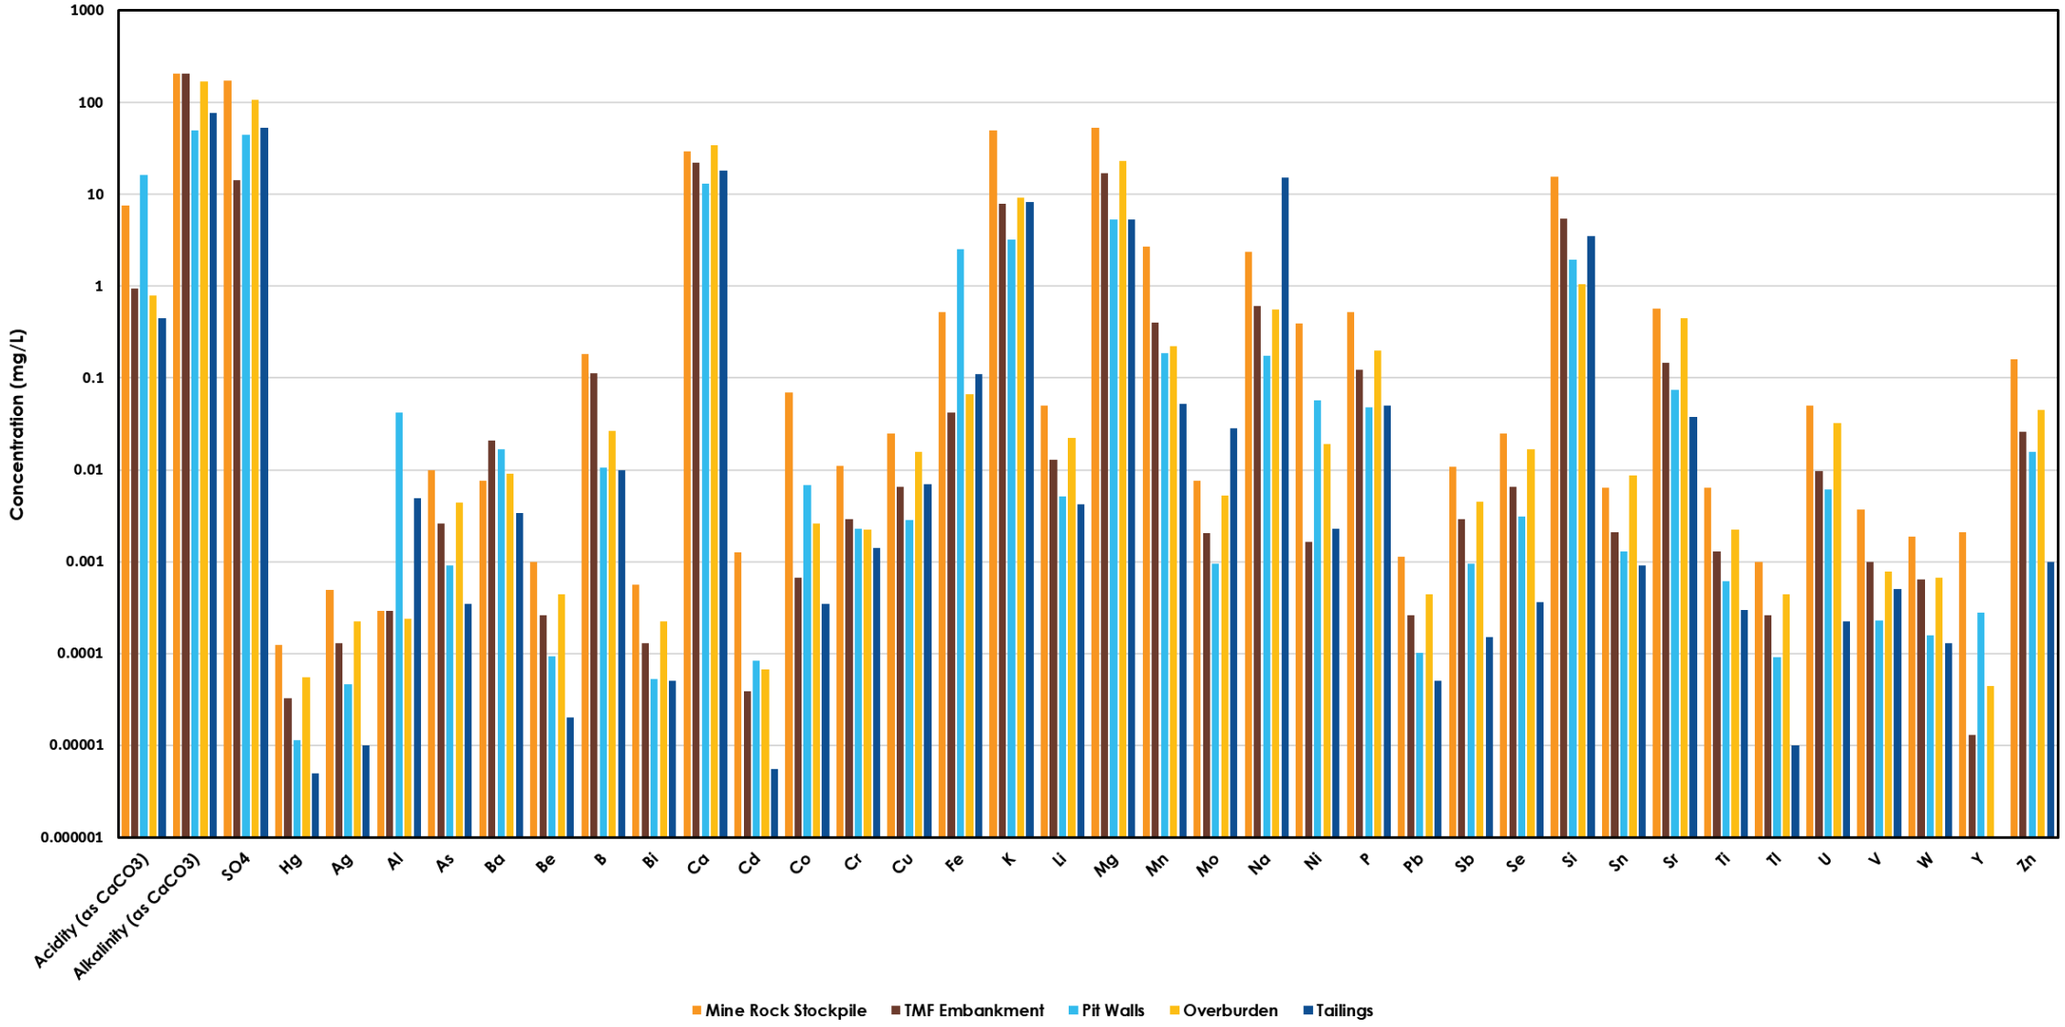

Figure 4.2: Concentrations at Closure for all constituents for source terms compared.

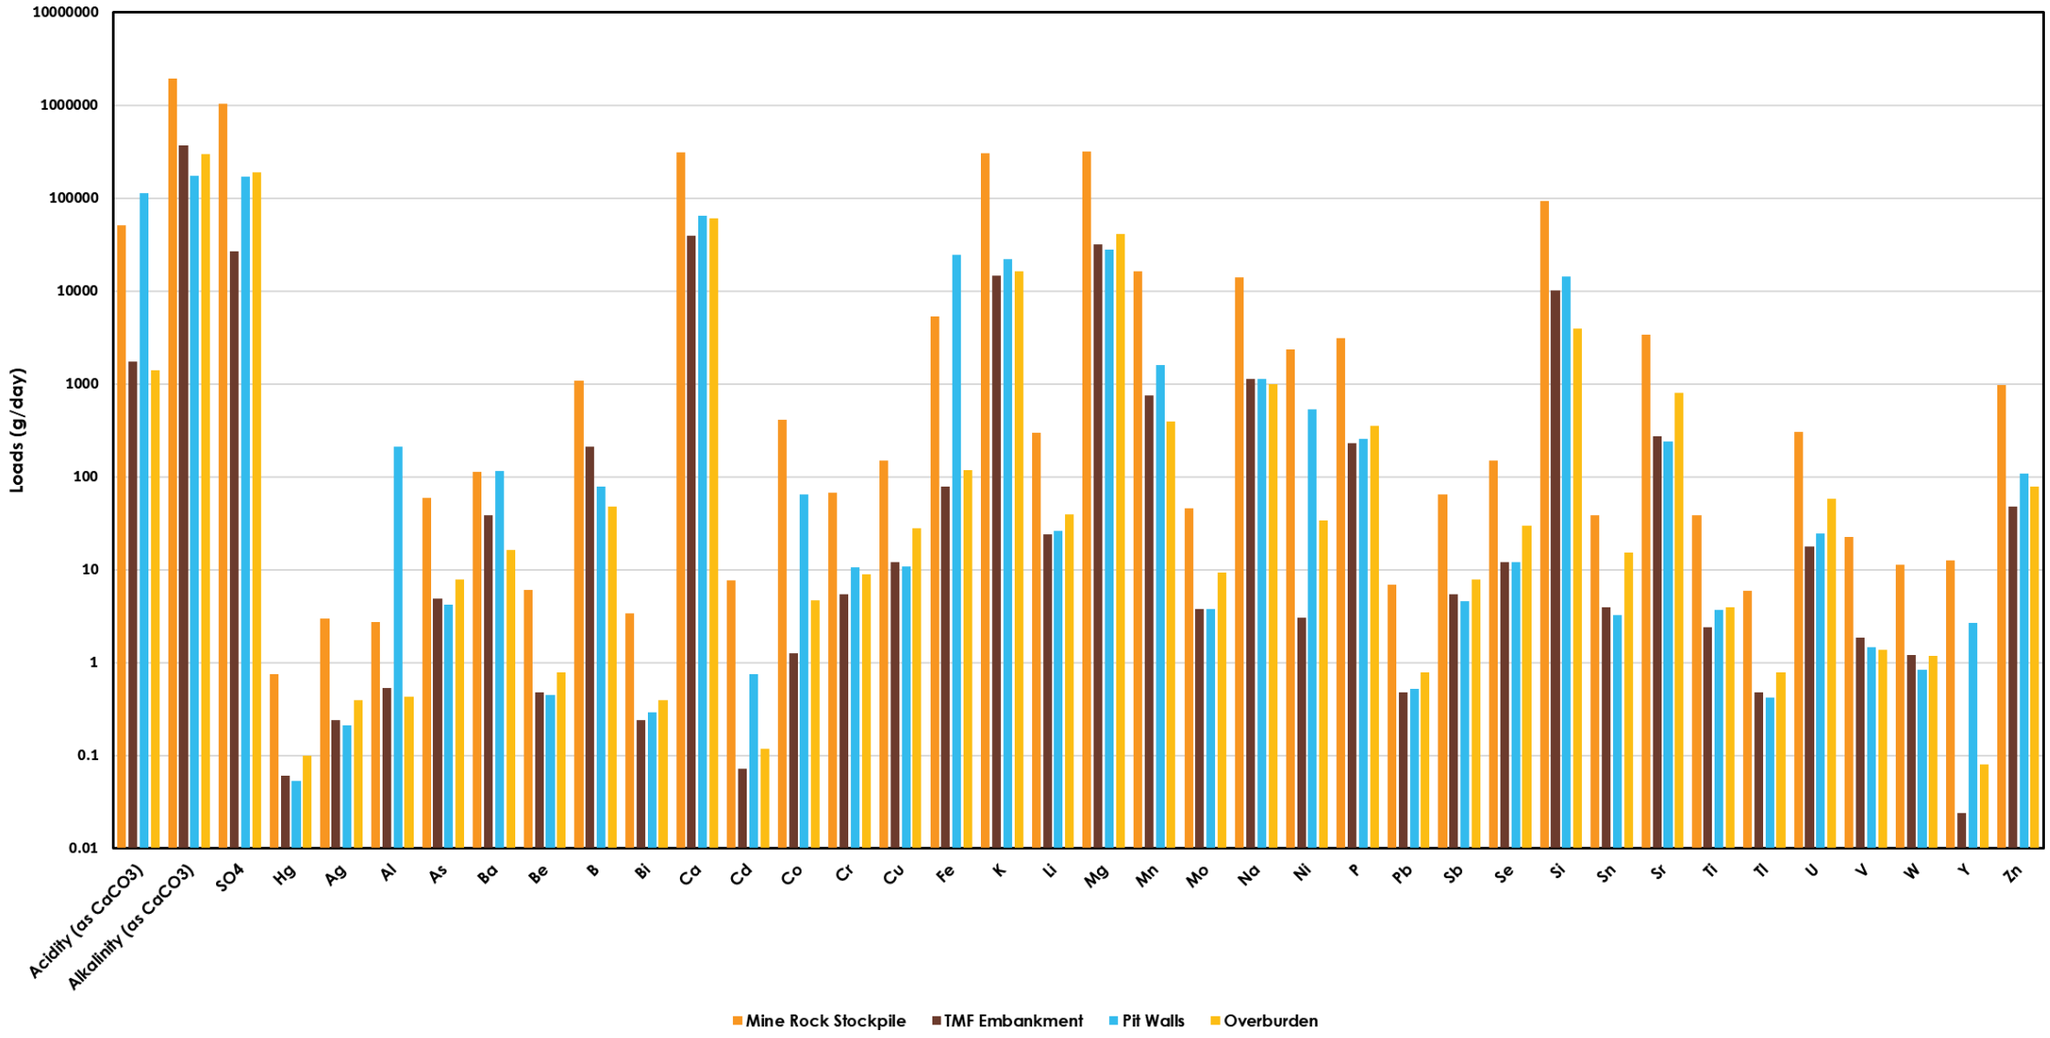

Figure 4.3: Loading rates at EOM for all constituents for source terms compared.

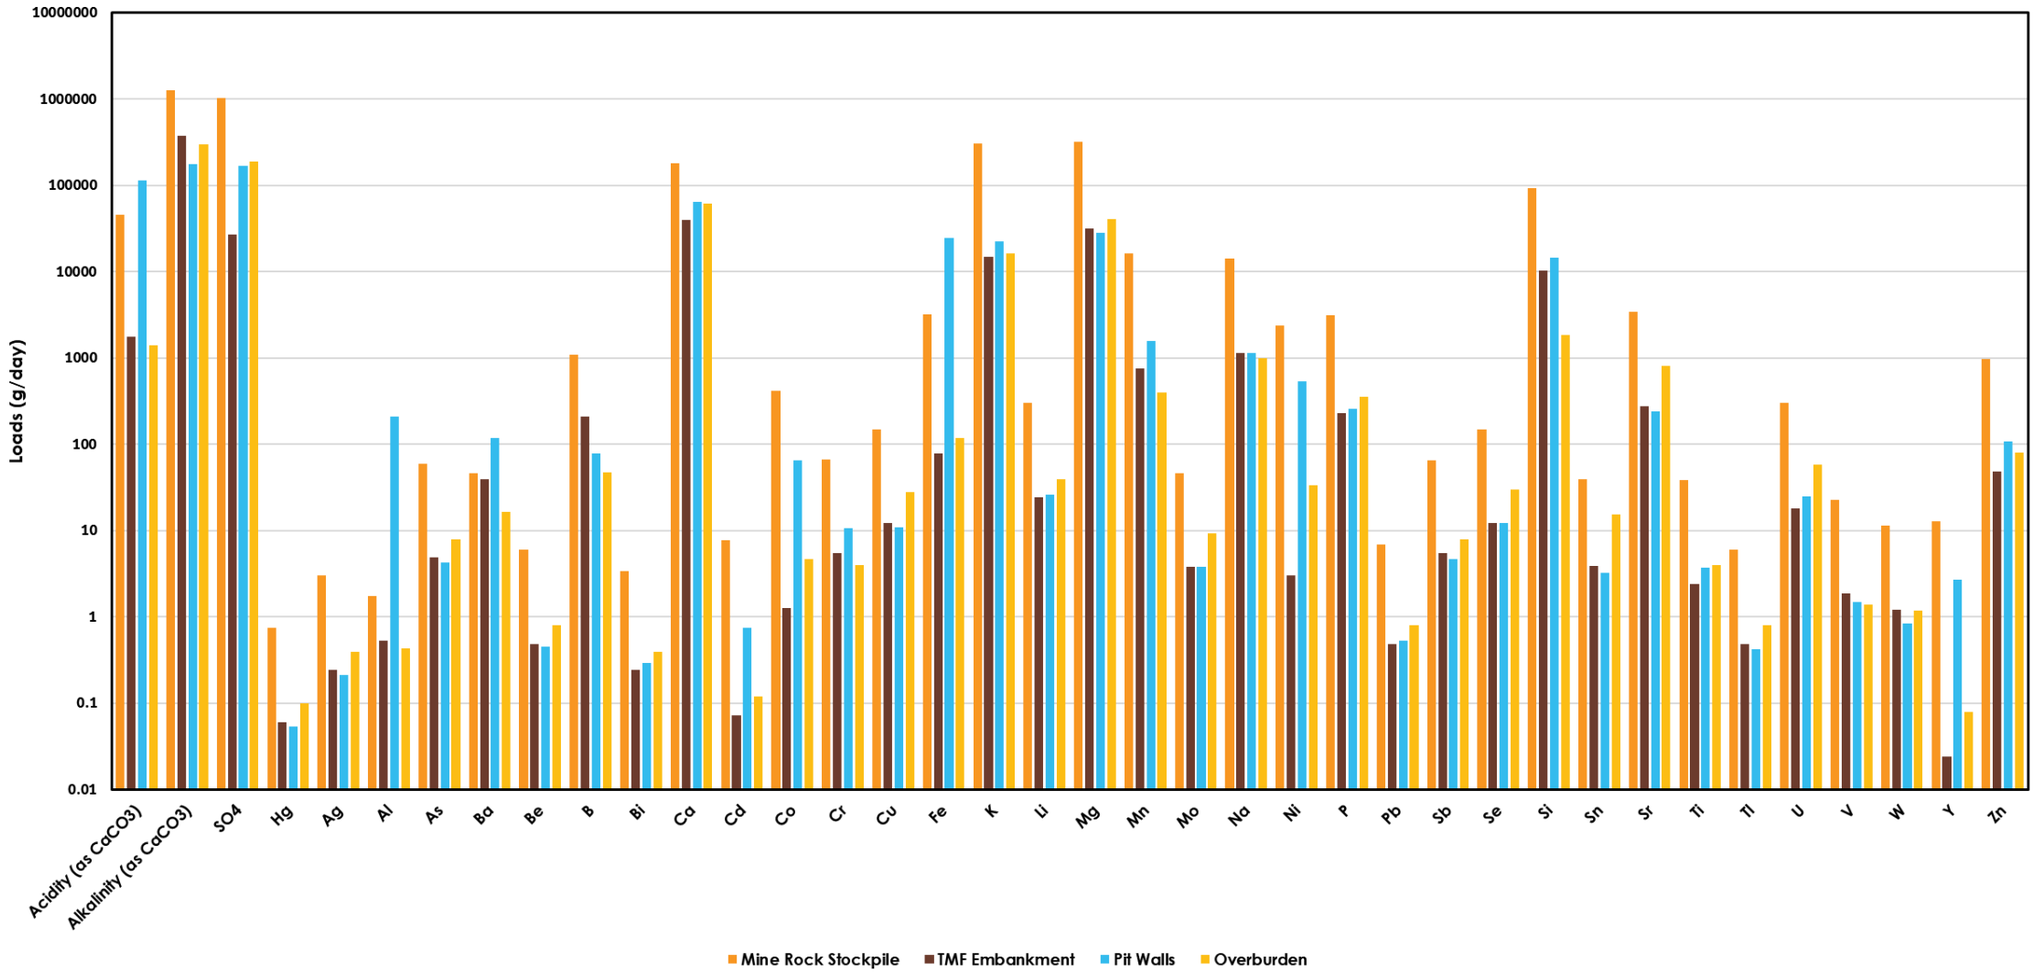

Figure 4.4: Loading rates at Closure for all constituents for source terms compared.

4.1 Seepage Volumes

Seepage volumes were provided by Lorax that were assumed to be representative of flows for the EOM timestep (2050) and Closure timestep to check source term concentrations and ensure loading rates are reasonable and were compared to other datasets available (i.e., water quality measurements at Bloom Lake). Both the footprint areas (Table 4.1) and water year annual seepage or runoff rates (Table 4.2) for each facility were used in the calculations.

Table 4.1: Facility footprints or planar area used to calculate flow rates.

Mine Storage Facility	EOM Footprint (ha)	Closure Footprint (ha)
Overburden Stockpile	160	160
Mine Rock Stockpile	542	542
Pit Surfaces	300	49
TMF Embankment	96	96

Values provided by and confirmed with Lorax.

Table 4.2: Flow rates used for calculating concentrations of source terms.

Mine Storage Facility	EOM Flow Rate (L/year)	Closure Flow Rate (L/year)
Overburden Stockpile	622,077,000	648,022,000
Mine Rock Stockpile	3,701,059,000	2,196,885,000
Pit Surfaces	1,619,028,000	278,253,000
TMF Embankment	656,545,000	681,121,000

Values provided by and confirmed with Lorax.

4.2 Mine Rock and Overburden

Constant loading rates for water quality parameters for the Mine Rock Stockpile and Overburden Stockpile were provided to Lorax to be entered into the WBWQM. Some additional details for these results are described in the subsections below. As noted, source terms were calculated using results of existing HCTs. If HCT concentrations were reported below detection limit, the detection limit was used. Results from an earlier version of the WQWBM indicated that Se and Hg were in exceedance of water quality guidelines when source terms were scaled from detection limit values for these constituents. Scaling up from detection limits can artificially increase source terms; therefore, in the source terms provided in this report, Se and Hg results reported as below detection limit were replaced with the detection limits in the latest HCTs completed by Okane (2024d), i.e., 0.000005 mg/L for Hg and 0.0005 mg/L for Se. These new detection limits from Okane (2024d) are also half the Stantec (2013) detection

limits. Lowering the detection limits for Se and Hg was considered justified in this case due to the high number of reported detection limit values for these species in mine rock (Table 4.3).

A summary of the occurrence of values that were equal to or below detection limits for all measured parameters reported by Stantec (2013) are included below (Table 4.3). If higher percentages of values reported as equal to or below detection limit exceed water quality criteria in the WQWBM, they may be re-evaluated to determine if the effects of scaling are artificially increasing source terms (bolded if greater than 80% in Table 4.3) similar to Se and Hg. If detection limits are labelled as 'not reported', a detection limit was not reported in the dataset provided by Stantec (2013). Future kinetic field bin studies that can be used to calculate loading rates at the field scale without the same application of scaling factors may be useful in future model iterations for any issues of source term exceedances due to scale up.

Table 4.3: Percentage of measurements in HCTs equal to or below detection limits reported by Stantec (2013) for different parameters.

Parameter	Detection Limit (mg/L)	Percentage of measurements equal to or below detection limit

4.2.1 Mine Rock Stockpile

Results for the median loading rates calculated from each formation at the laboratory scale used for the Mine Rock Stockpile source terms are shown in Figure 4.5 to Figure 4.9. Results from the first six weeks of HCTs were removed from these figures as they represent flushing of initial oxidation products. Humidity cell test data by formation shows a wide spread of loading rates (sometimes over an order of magnitude) within the Katsao, Menihek, and Sokoman Formations (Figure 4.5, Figure 4.6, Figure 4.8). Variation in metal release rates (specifically Co, Cd, Cu, Fe, Ni, and Zn) highlight the increased metal leaching from sulfide mineral oxidation if mine rock becomes acidic and sulfide oxidation rates increase, but also natural variation due to heterogeneity and greater or less abundance of minerals in different HCTs under neutral or acidic conditions. Other parameters, such as As and Se, are also associated with sulfide oxidation but may be more mobile at more neutral pH ranges. Tabulated results for all parameters measured in the HCTs are provided in Appendix B, and are discussed in greater detail by Stantec (2013). Calculated scaled loading rates for the Mine Rock Stockpile are provided in Table 4.4, with concentrations calculated using flow data provided by Lorax (Table 4.2) reported in Appendix E.

In the case of Se, detection limits in the HCTs from Stantec (2013) of 0.001 mg/L are equivalent to the Canadian Council of Ministers of the Environment (CCME) freshwater aquatic guidelines and produced

seepage concentrations ranging between approximately 0.03 to 0.08 mg/L after scaling up. Although the detection limits were decreased for Se and Hg as noted previously, when scaling up source terms the seepage quality calculated will still exceed CCME guidelines – whether this will result in water exceeding water quality guidelines before entering the receiving environment will be assessed in the WQWBM. Additional kinetic studies at the field scale may be beneficial for understanding the loads and concentrations anticipated from the blended Mine Rock Stockpile.

A single blended HCT is currently ongoing to investigate the benefits of the blended Mine Rock Stockpile construction method on overall loading rates (Okane, 2024d). Although preliminary results of this blended HCT have not been used to support the development of source terms in this report, the weighted median laboratory-scale loading rates used for the development of source terms described above are compared to the initial results of the blended HCT below (Figure 4.10). This comparison shows how for some metals (e.g., Co, Cr, Cu, Fe, Ni, Zn) appear much lower under neutral conditions compared to the weighted loading rates where lowered pH conditions in individual HCTs increase sulfide oxidation rates and result increased metal mobility. This comparison suggests the proposed construction design and achieving adequate blending will be important for managing potential metal release risk from the Kami mine rock. However, results of kinetic tests showing the effects of blending are currently only available at the laboratory scale. At the field scale, it may be more challenging to ensure adequate availability of NP and prevent acidic pockets from developing throughout the Mine Rock Stockpile. The uncertainty will be addressed with additional kinetic testing at field scale once sample material becomes available.

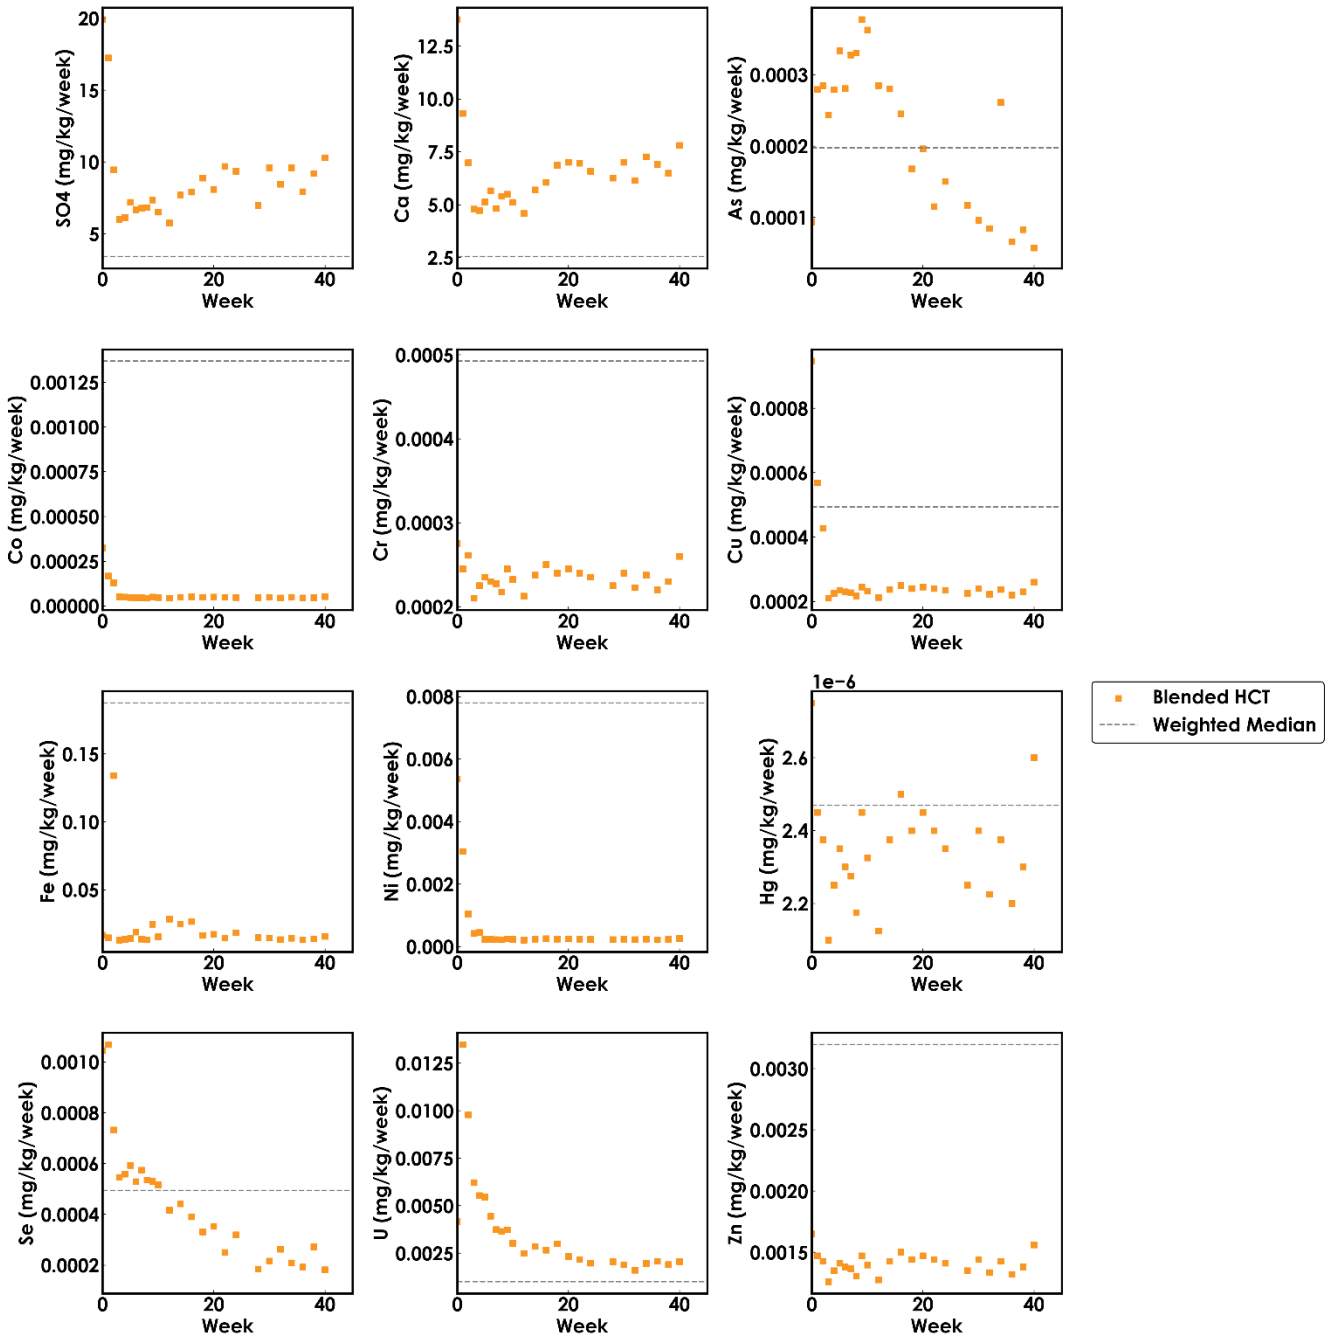

Figure 4.10: Weighted calculated HCT loading rates compared to blended HCT for Mine Rock Stockpile.

Okane, 2024d.

4.2.2 *Overburden Stockpile*

Calculated source term loading rates Overburden Stockpile are shown in Table 4.5. As the overburden source terms were derived from a single HCT and results were mostly stable throughout the 41-week test, parameters had weekly loading rates that were within an order of magnitude (Figure 4.11). The HCT used for the overburden loading rates is a composite of two overburden samples, ROB11-18 #17 and ROB11-09 #23. In looking at the ABA results from these two samples (Okane, 2024b), the sample ROB11-09#23 had paste pH of 4.19, and total S content of 0.9%. Seven of the 71 overburden samples analyzed had paste pH < 6.5, indicating acidic conditions at the onset, while 10 out of 71 samples had total S > 0.1%. This suggests that the overburden HCT used to generate source terms results may overestimate metal release for the Overburden Stockpile due to the association of higher sulfide content and metal release.

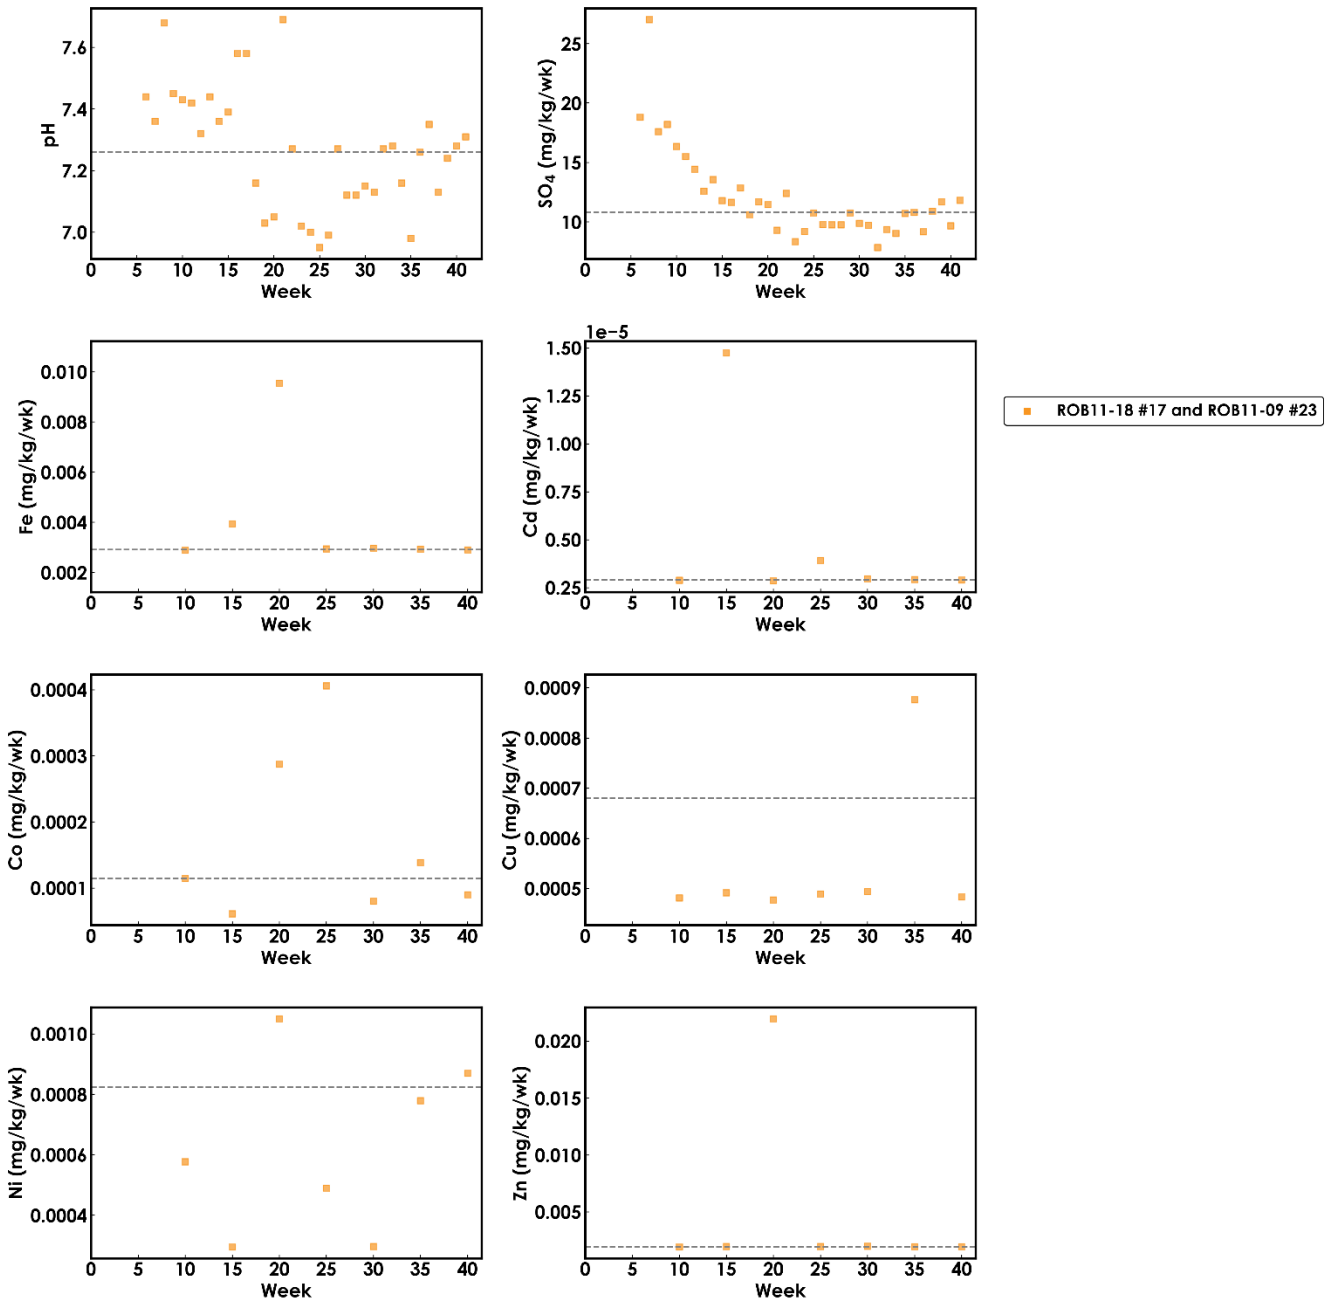

Figure 4.11: Overburden selected parameter loading rates compared to Stantec (2013) HCTs.

Dashed line represents median loading rates based on leachate from HCTs collected in the last six weeks for the rock formation.

4.3 Pit Surfaces

As noted in Section 3.3, the pit surfaces loading rates were developed based on weighted PAG and NPAG contributions, estimated from different formations. Median loading rates before scale factors were applied used to represent PAG and NPAG contributions are shown compared to HCT loading rates (Figure 4.12). Scaled pit surface loads are provided in Table 4.6. Figure 4.13 shows these source terms for select species compared to pit water quality measurements from Bloom West Pit (FBW). Pit water annual concentrations were calculated using annual flow volumes from runoff provided by Lorax. Along the pit surfaces, there is direct runoff and less opportunity for mixing of waters, therefore it is assumed that all the PAG rock exposed on the pit surfaces will generate acidic loads and not undergo secondary mineral precipitation. Final loads and source terms were provided for input into the WQWBM as values in five year increments to account for changes in exposed portions of PAG, NPAG, and overburden pit surfaces (Appendix E).

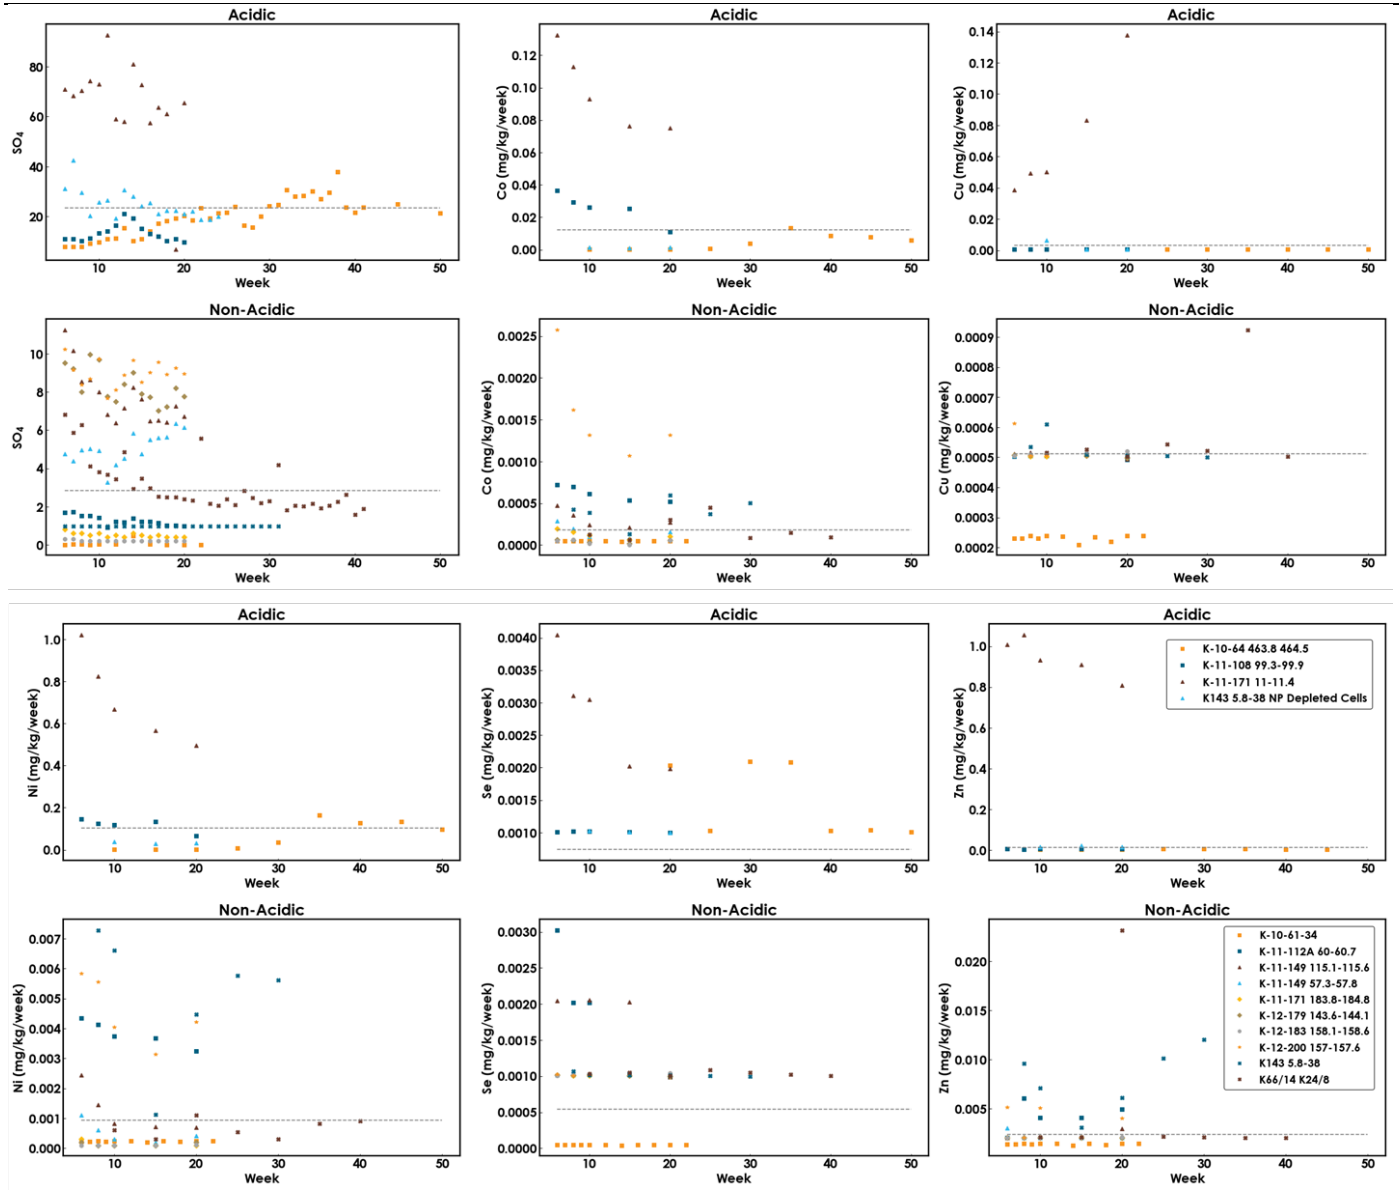

Figure 4.12: PAG and NPAG source term loading rates calculated from acidic and non-acidic HCTs, respectively.

Table 4.6: Pit surface loads at EOM and Closure.

4.4 Tailings

4.4.1 TMF Dam Embankment

The TMF Dam Embankment mine rock was assumed to be composed of 50% Sokoman (Figure 4.6) and 50% Wishart Formation (Figure 4.7). Scaled loading rates for crushed mine rock from the TMF dam embankment are provided in Table 4.7. For the TMF dam embankment, there was assumed to be no changes between EOM and Closure besides some changes in seepage due to climate, since no cover will be placed on the dam. Differences in flows through the dam due to changes in water table elevation height within the dam have not been considered in this iteration.

Table 4.7: TMF dam embankment loads at EOM and Closure.

4.4.2 Tailings Water

Values for the tailings water quality from measured supernatant samples were provided as fixed concentrations, rather than loads. Okane (2024b) discusses the laboratory results for gravity flotation tailings which showed high total N concentrations in the supernatant that could not be explained by the other species measured (i.e., NO_3, NO_2, and NH_3). Soutex noted the addition of coagulants in the gravity and magnetic flotation streams (Appendix A), which may be a source of N from amines within the coagulants. The gravity and magnetic flotation streams make up approximately 7% of the total solids and the supernatant from these streams represents approximately 10% of the water in the TMF; the supernatant samples reported here represent a blend of flotation streams expected through LOM. Additional N from other species added in the milling process may not have been captured in these source terms, and should be re-evaluated in future iterations of the model when additional samples become available.

Table 4.8: Tailings source terms from supernatant water samples.

4.5 Nitrogen Results

For sources where N species were assumed to be controlled by residual N from blasting (i.e., Mine Rock Stockpile, TMF Embankment, and pit surfaces), NO_3, NH_3, and NO_2 were calculated each year and provided to Lorax for input in the WQWBM. These results are included in Appendix C, while the calibrations for the Bloom Lake model are in Appendix D. Below, forecasted N species for Kami compared to Bloom Lake measured results are shown for the Mine Rock Stockpile and Pit surfaces (Figure 4.14). Calculated concentrations from Kami appear lower than Bloom Lake measurements; this is due to the fact that calibrations were made first to Bloom Lake for the Bloom West Pit and Principal Stockpile, where then the same N loss terms and leaching efficiency were applied to the Kami mine rock schedule and reduced powder factors anticipated at Kami.

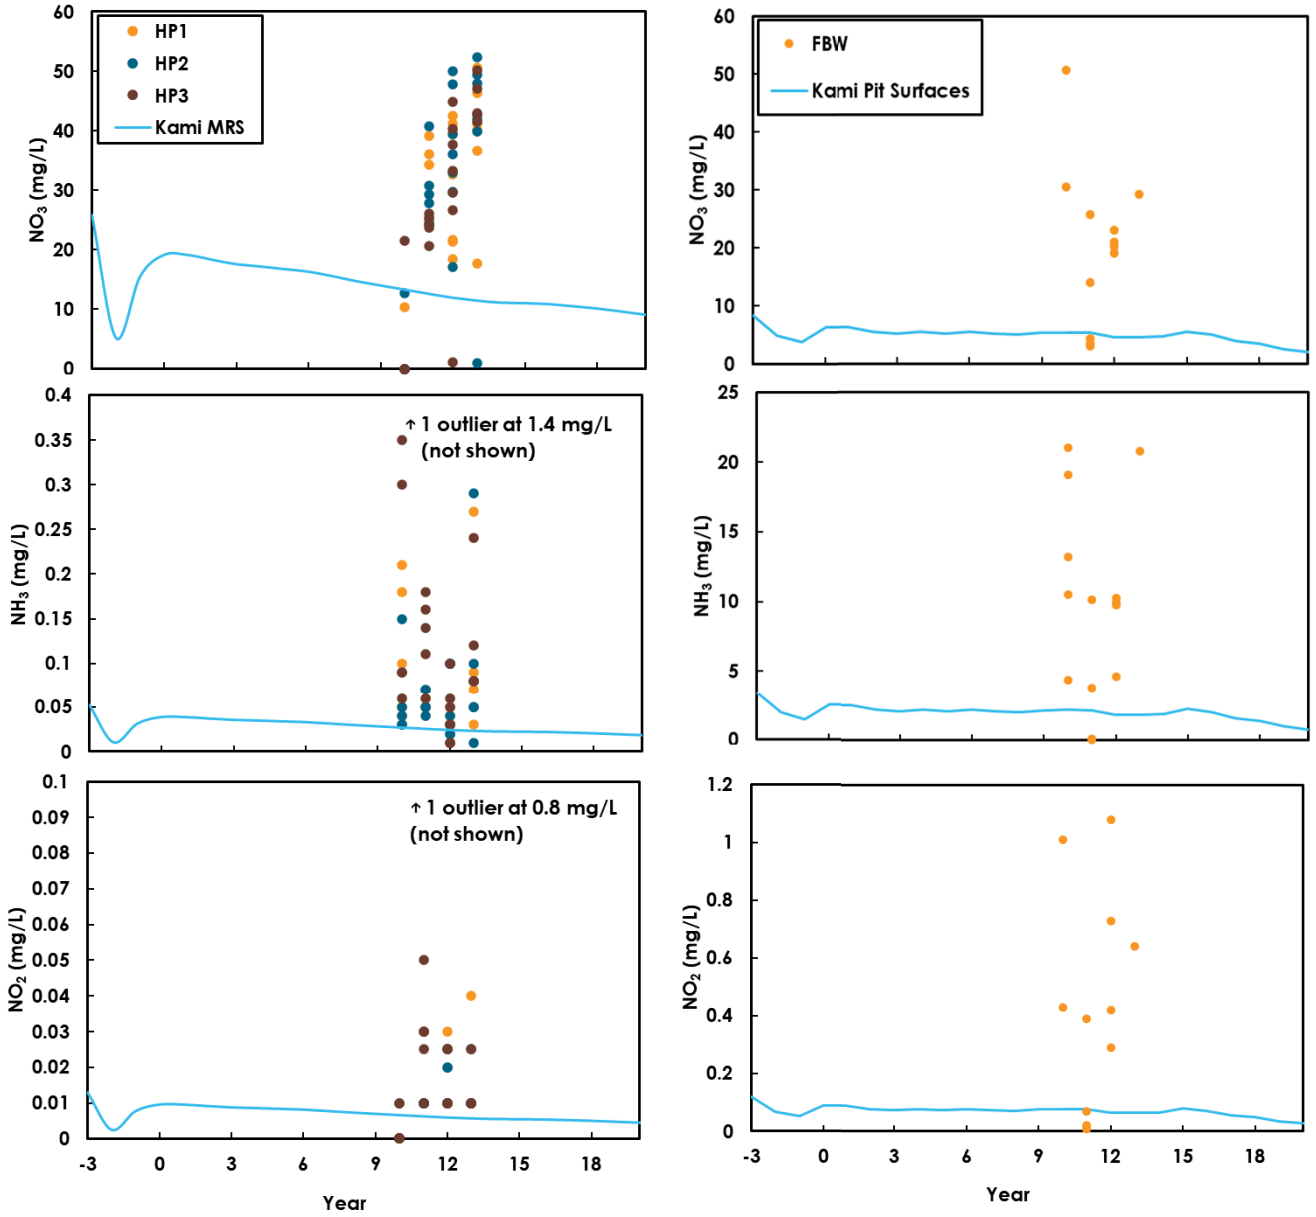

Figure 4.14: Kami Mine Rock Stockpile (left) and pit surfaces (right) calculated N concentrations compared to measured Bloom Lake Data

HP = Principal Stockpile seepage; FBW = Bloom West Pit water samples.

5 ASSUMPTIONS AND LIMITATIONS

Source terms for the Mine Rock Stockpile were developed using median loading rates for each rock formation from 14 HCTs provided by Stantec (2013) and one HCT from Okane (2024d), which were then weighted using the anticipated rock tonnages for each respective formation to be placed in the Mine Rock Stockpile (Table 2.1). Assumptions and limitations for this method are summarized below:

- Humidity cell test data by formation shows a wide range of loading rates (sometimes over an order of magnitude) within the Katsao, Menihek, and Sokoman Formations, where this variation in metal release rates (specifically, Co, Cd, Cu, Fe, Ni, and Zn) highlight the risk for metal leaching if mine rock becomes acidic. In the development of the loading rates, no acidic HCT loading rates were captured. It is assumed that Champion will undergo measures to ensure adequate blending of mine rock is feasible to avoid the formation of acidic pockets developing within the stockpile. If localized acidity forms, increased metal leaching is likely to occur which may require additional mitigation.

- Approximately 31% of the rock that will be placed in the Mine Rock Stockpile is classified as PAG or Uncertain (Table 2.3). These estimates may vary as additional sample locations are tested for geochemical characterization. Limitations of sample availability are expected at this stage in the project and will be addressed in future stages of the mine development.

- Loading rates for the Mine Rock Stockpile were developed using the formation weighting anticipated at the EOM timestep. Variations in the Mine Rock Stockpile composition by formation could also result in differences in metal release rates, even under neutral conditions, if there is a larger proportion of rock associated with metal release (e.g., Menihek or Katsao Formations) in the Mine Rock Stockpile at earlier stages of the mine.

Assumptions and limitations associated with the Overburden Stockpile:

- Overburden source terms were developed from a single HCT consisting of two samples, one which has higher sulfide content than what is represented by a larger suite of static tests and ABA results (Okane, 2024b). Due to the association of metals (e.g., As, Cd, Co, Cu, Fe, Ni, Se, Zn) with sulfide minerals, some of the overburden metal release rates provided in this report may be higher than what is expected to be representative.

Uncertainties associated with the pit surfaces:

- Calibration for the Kami pit surfaces was made using Bloom West Pit. Uncertainties that were noted in the Bloom Lake model (Okane, 2024c) influence the calibration of the reactive depth assumed for the Rose Pit surfaces. Updates to the pit surfaces source terms, such as the differentiation of reactive depth of the walls compared to benches, may be made by refining the Bloom Lake model, or when site-specific measurements at Kami become available during Operations.

With respect to the TMF Embankment:

- The TMF Embankment will be constructed of NPAG rock. In this report, it was assumed that 50% of that NPAG rock will be sourced from the Sokoman Formation, and 50% of the NPAG will be sourced from the Wishart Formation, as these rock formations have greater abundance and consistency of NPAG material availability. However, other considerations for use of these rock formations (e.g., availability of material, geotechnical properties) were not considered in this assumption.

With respect to the tailings supernatant source terms:

- Concentrations from supernatant from a blend of gravity flotation, cobber, and finisher tailings streams were used as the tailings source term for both the EOM and Closure time steps. It was noted that supernatant is likely representative of water leaving the tailings during Operations but may not be representative as water levels drop and milling no longer recirculates tailings water into the TMF.

- Nitrogen and amines present in the other additives (collector, coagulant, and flocculant) may be added to the tailings which have not been considered here, making it challenging to accurately estimate the total N coming from the tailings with the information available at the time of developing these source terms.

Data limitations and assumptions associated with N species:

- Nitrogen loading for mine rock was calculated using the methods presented by Ferguson and Leask (1988). These methods were derived from coal mining, where high N loss is considered in the equations provided for wet conditions. As technology has changed and methods from Ferguson and Leask (1988) were derived using site-specific conditions to the Elk Valley, BC, it is expected that the values related to N loading will be different at Kami. We have used field scale results from a WQWBM at Bloom Lake (Okane, 2024c) (Appendix D) to modify the N from blasting residual content, distribution of N between pit surfaces and mine rock stockpiles, and the species distribution amongst total N. The distribution of values related to N loading rates from Bloom Lake are thought to be more representative of Champion's blasting methodology and practice than Ferguson and Leask (1998). While the conditions at Bloom are assumed to be similar at Kami, differences in flow pathways and the redox conditions, changes between blasting practices at site, may result in differences observed in the field than calibrated values reported here.

- At this time, the effect of residence time on N speciation is unknown. Nitrogen species may be reassessed in the future to further investigate timing of flushing and loss of residual N from blasting through the total thicknesses of the Mine Rock Stockpile and TMF embankments, which was not considered here.

Other assumptions and limitations of methods used to calculate source terms:

- While constant source terms were provided, mineral weathering and the associated release of metals will likely change over time. Solubility controls and neutralization of acidity from leachate from higher risk units (such as the graphitic mica schist) mixing with higher NP rock types were not considered for these loading calculations. Under higher pH conditions, some metals may be attenuated through mechanisms such as secondary mineral precipitation and adsorption, while others may be released. As geochemical reactions are complex and interdependent on multiple parameters, it is challenging to calibrate these models to forecast meaningful results without representative laboratory or field scale data at this stage. Attenuation mechanisms may be considered in future source term development when additional supporting data is available.

- Effects of oxygen limitations were not considered. As mine rock will be crushed in-pit and transported by conveyor belt, lower air permeability from crushed rock may limit oxygen ingress into the Mine Rock Stockpile, which may limit sulfide oxidation (resulting in less acidity and metal leaching released) dependent on placement location. Conversely, crushing rock may increase reactive surface area of mine rock, leading to greater release rates.

- It is noted that all storage facilities within this memorandum had at least one parameter equal to the detection limit for the source term derivation. While use of the detection limit is accepted practice, the value of detection limits provided in Stantec (2013) were in some instances equivalent to current CCME guidelines (specifically noting Se in this case). Although scaling factors applied decrease loads from laboratory to field scale for factors such as grain size, temperature, and channelization, when scaled up given the large volumes of rock anticipated at the Kami Project, a detection limit value of 0.001 mg/L from HCT leachate results in calculated seepage concentrations of 0.03 to 0.08 mg/L. Based on preliminary results from the blended HCT (Okane, 2024d), we have lowered the detection limit for Se and Hg to half the DL reported by Stantec (2013) to match the detection limit of new tests completed by Okane (2024d); however, this may still result in exceedances of water quality guidelines in the WQWBM. Additional kinetic studies at larger scales (such as field bin tests) may reduce uncertainties in loading rates at the field scale before full-scale seepage data becomes available.

6 RECOMMENDATIONS

With respect to the source terms, the following recommendations are provided for potential future source term refinements:

- Kinetic field bin tests composed of different blends of expected mine rock over the life of mine are recommended to test the feasibility of achieving perfect blending with larger grain sizes and different compositions of rock.

- It was shown that NPR values suggest the Mine Rock Stockpile will remain classified as NPAG through the entire life of mine; however, loading rates may vary between different rock formations. Source terms that consider changes in weighting of the different rock formations due to the extraction schedule throughout the mine life should be considered in future model iterations. Kinetic field bins recommended above will be useful for the development of these different mine phase loading rates.

- To address the impact of crushing mine rock on metal release rates from the Mine Rock Stockpile, target crush size should be evaluated in kinetic field bin studies. Evaluation of target crush size will help address uncertainties in scaling factors and crushed rock reactivity.

- Additional kinetic column tests at a laboratory scale would also support understanding of the range of potential loading rates from mine rock formations that have a wide range in metal release rates in the current dataset.

- Depending on the results of laboratory analyses, ongoing geochemical kinetic test work as part of the geochemical characterization program (Okane, 2023) using lower detection limits relative to the dataset provided by Stantec (2013) for potential contaminants of concern identified by the WQWBM may help support the basis for decreasing source term values. Additional kinetic testing (such as more HCTs, field bin tests, or customizable columns) that represent more site-specific conditions and target lower detection limits for leachate analysis may be beneficial to support this investigation. Specifically, larger kinetic tests such as field bins will not require the same scaling factor application at the HCT scale and may be beneficial to detection limit issues noted here.

- Sensitivity studies to capture uncertainty in loading rates of possible water quality outcomes should be considered in future iterations of the WQWBM.

- If statistically significant amounts of additional geochemical characterization data becomes available, the ABA block model may be updated to improve the block model resolution.

- A PAG and metal leaching management program will be developed to ensure sufficient NP is available to manage AP from the materials and manage potential metal leaching associated with certain rock types as material is extracted and placed in the Mine Rock Stockpile during the

Operations phase. The rock management program should involve a quality assurance/quality control (QA/QC) sampling program for mined materials to ensure sufficient blending is occurring during construction of the Mine Rock Stockpile, to mitigate the risk of localized acid generation in the stockpile that may result in increased metal release.

    - One potential method is performing onsite carbon and sulfur analyses of blast hole samples using a LECO furnace to estimate NP and AP of a mining block. Due to the presence of non NP-bearing carbon minerals such as graphite and siderite, site-specific correlations of total carbon and NP will need to be developed for a PAG management program to be successful.

- Additional kinetic studies, including laboratory HCTs and kinetic field bins for the overburden materials should be implemented to develop more representative overburden source terms.

- Tailings source terms should be updated with kinetic data when available and should consider total N loading from estimated applications during mine life of N-containing additives required for processing.

7 CLOSURE

We trust information provided is satisfactory for your requirements. Please do not hesitate to contact the undersigned at 437-684-4071 for further information or questions.

Appendix D

Bloom Lake Nitrogen Calibration Results and Kami Loads

Nitrogen calculations were completed using the method described previously. As conditions are assumed to be wet, a 100% emulsion product is used at Bloom. The emulsion product (Fortis™ Extra) is composed of 70 to 85% ammonium nitrate, 3 to 7% petroleum, and 0.05 to 1% sodium nitrite (Dorval A. (G Mining), *personal communication*, August 1, 2023; Orica, 2019). Since 100% emulsion is used, the equation by Ferguson and Leask (1988) for mines using greater than 20% emulsion can be simplified here to:

$$N_{tot} = 1.5\% \times \mathrm{R}_{Em} \times \mathrm{P}_N \times \mathrm{M} \quad \text{(Equation 1)}$$

Where,

N_{tot} = Total N residual from explosives (kg);

R_{Em} = the powder factor or explosive application rate for emulsion (0.40 kg/t for mine rock and 0.45 kg/t for ore) (Dorval A. (G Mining), *personal communication*, August 1, 2023);

P_N = mass proportion of nitrogen, assumed here to be 0.3 (using the values of 85% ammonium nitrate and 1% sodium nitrite in emulsion composition); and

M = tonnage of mined material (mined rock) (t).

In Table D.1, contributions of mine rock to the Principal Stockpile and ore by production year are noted. However, mining of the Bloom West Pit only began in 2018. It is Okane's understanding that all mine rock placed in the Principal Stockpile comes from the Bloom West Pit between 2018 to 2023 (i.e., no N was calculated for the Bloom West Pit prior to 2018).

The $N_{inventory}$ is updated annually with more waste rock placed. The total nitrogen dissolved each year is a function of the $N_{inventory}$ multiplied leaching efficiency, assumed to be 90% based on work by Mahmood et al. (2017). The dissolved N is then converted to a concentration by dividing by the total Halde Principal (Principal Stockpile) porewater estimated in storage, which is a function of the volume of rock multiplied by the volumetric water content (Equation 2).

$$N\ Concentration\ \left(\frac{mg}{L}\right) = \frac{N_{inventory}\ (mg) \times LE}{\frac{(V_R \times VWC)}{1000}} \quad \text{(Equation 2)}$$

Where,

V_R = volume of rock (m^3);

VWC = volumetric water content; and

LE = leaching efficiency of 90%.

Some of this N is removed annually in seepage (calculated as the concentration of nitrogen multiplied by the seepage volume), which was used to update the annual inventory of nitrogen remaining in the stockpile.

The modified values used in the Ferguson and Leask calculation method are compared to concentrations measured from Halde Principal at Bloom Lake are shown in Figure D.1. Concentrations were calculated using N loads calculated above divided by monthly seepage flow rates (which considers recoverable and unrecoverable calculated seepage for the entire Principal Stockpile).

Pit wall seepage rates (which consider N blasting residual in mine rock and ore) were compared to pit water sampled from the Bloom West Pit to calibrate (Figure D.1). Annual flow rates of 217,209,000 L/year from average reported values by WSP (2021, 2022, 2023) were used to calculate the pit wall concentrations used to calibrate to the FBW (Bloom West Pit) water quality sampling point (Figure D.2).

Table D.1: Annual tonnages mined for the Principal Stockpile and Bloom West Pit.

Year	Mined Mine Rock (t/year)	Ore Mined (t/year)	Mine Rock to Principal Stockpile (t/year)
2011	19,087,678	12,782,771	15,978,464
2012	19,087,678	12,782,771	15,978,464
2013	19,087,678	12,782,771	15,978,464
2014	19,087,678	12,782,771	15,978,464
2015	19,087,678	12,782,771	15,978,464
2016	19,087,678	12,782,771	15,978,464
2017	4,486,839	3,147,733	4,112,627
2018	4,486,839	3,147,733	4,491,500
2019	15,000,753	5,842,434	5,847,605
2020	19,219,019	7,054,789	7,336,648
2021	19,682,820	9,743,174	6,835,961
2022	23,285,603	11,300,542	4,673,490
2023	20,979,020	15,414,332	5,926,750
TOTAL	221,666,961	132,347,364	135,095,365

Tonnages provided by Quebec Iron Ore. Annual tonnages between 2011 to 2017 were assumed to be consistent as only final tonnages were available.

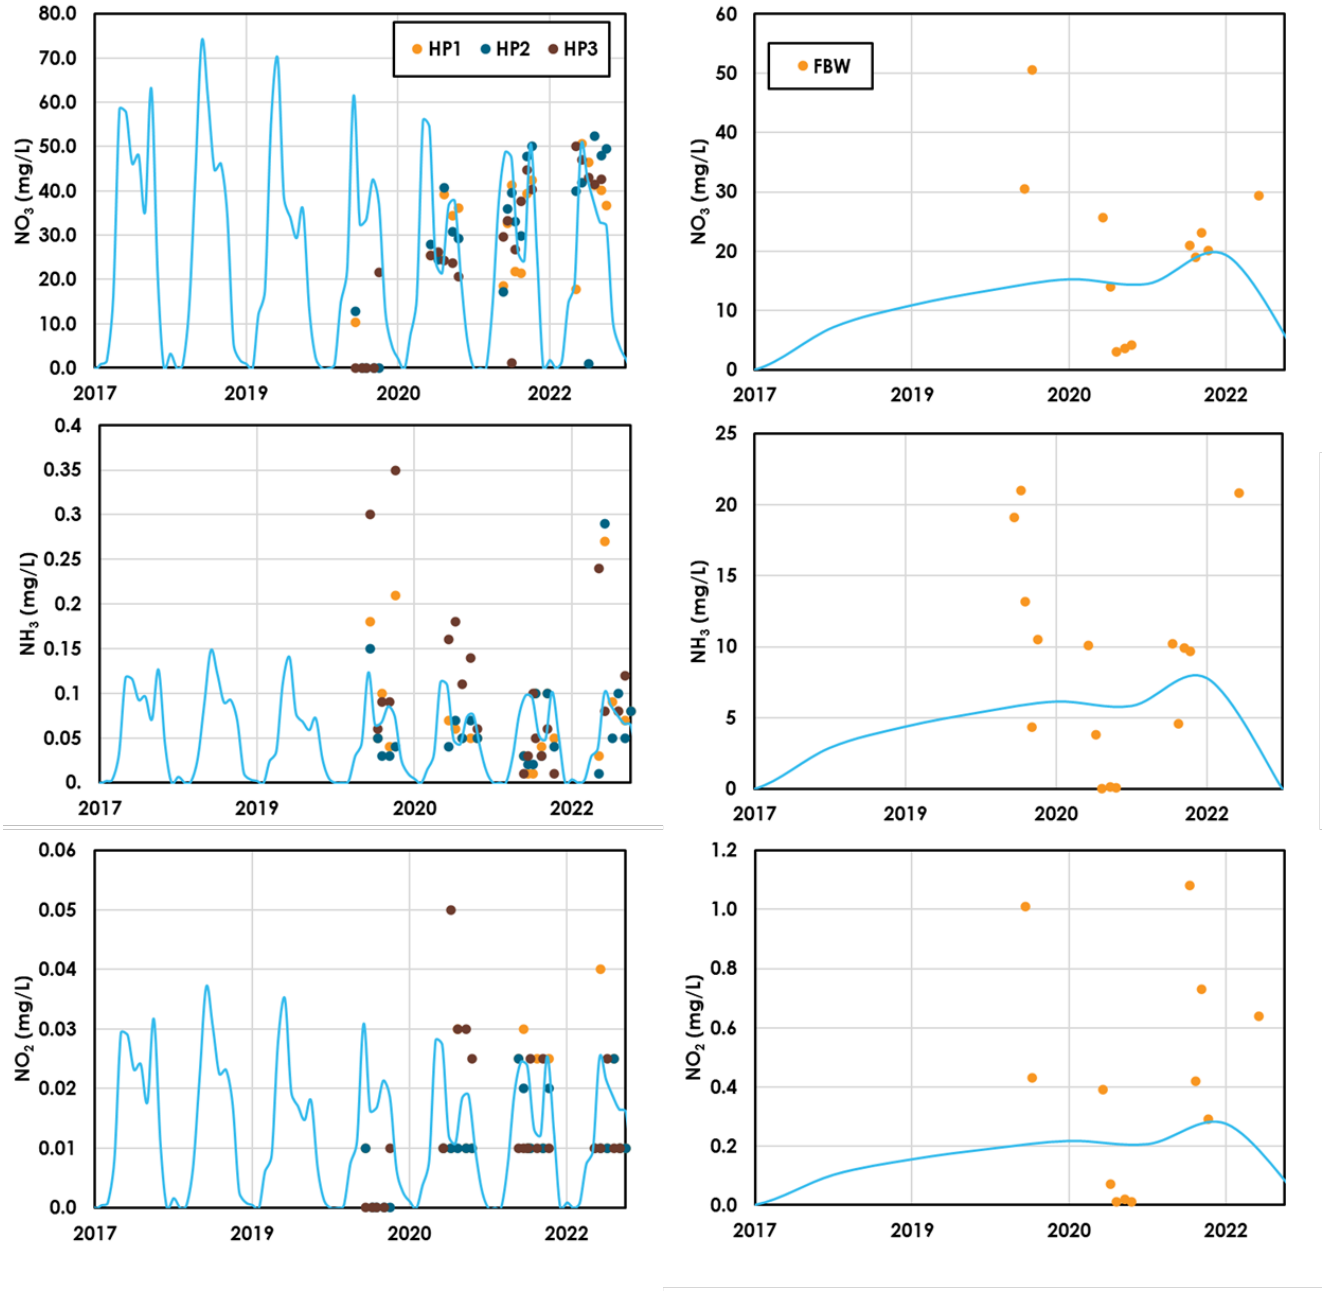

Figure D.1: Nitrogen loads calibrated to seepage sampling points for Halde Principal (left) and Bloom West pit (right) at Bloom Lake.

Appendix D:
Duley Lake Conceptual Site Model

CHAMPION IRON

MEMORANDUM

To: Kami EA File **Date: 2 April 2025**
From: Jérémie Bonneau **Project #: A703-3**
Subject: Assimilative Capacity Assessment of Duley Lake

1. Introduction

2. Limnological Aspects of Duley Lake

2.1 Inflows and Outflows

Duley Lake has a volume of 78,000,000 m^3, an average depth of 7.3 m, and a maximum depth of 30 m. The main natural inflows are the Waldorf River and Mills Lake at the south end and the Walsh River at the north end. The outflow is located at the north end, near the Walsh River inflow. This configuration suggests that the water from the Walsh River enters and directly exits Duley Lake, confined to the shallow bay at the north end of the lake. It therefore does not induce a hydraulic flow through Duley Lake and is not efficient at renewing the lake's water.

Table 1:
Average monthly inflows in Duley Lake during operations

Month	Duley Lake Inflows during mine operations (/1000 m^3/month)					
	Waldorf River to Duley Lake	Mills Lake to Duley Lake	Riordan Lake to Duley Lake	Walsh River to Duley Lake	Natural Catchment Runoff	TSF and Pit Sed Pond to Duley Lake

Yearly	38400	26800	5500	424500	40000	27500

2.2 Seasonal Stratification, Currents and Ice Cover

Observations show that Duley Lake becomes stratified in summer, with a warm upper layer (epilimnion) and a colder bottom layer (hypolimnion) (Figure 1). These two layers have different densities, limiting the vertical exchange. This created hypoxic conditions in the deeper part of the lake (>20 m) in September 2024. Considering mean wind speeds around 4 m/s in Labrador City and at Wabush airport, lake currents should be around 2 cm/s in average over the epilimnion (higher near the surface, lower near the bottom). In the fall, when the air temperature decreases, the lake becomes homogeneous (same water density from the surface to the bottom) and the whole water column mixes vertically. Ice cover forms in November and persists until April. Under the ice cover, water temperature should be around 4°C from the bottom to around 1 m below the ice cover, where is cools to 0°C at the ice-water interface. However, no winter observations are available at the moment to confirm this. Since wind does not act on the lake in winter because of the ice cover, currents are slower. Using the hydraulic flow from the Waldorf River and Mills Lake in winter, this yields a south-to-north hydraulic current around 0.04 mm/s. In April, the ice cover melts and wind becomes important again. The lake density will be homogeneous until the summer epilimnion is formed by warm air temperature and solar radiation.

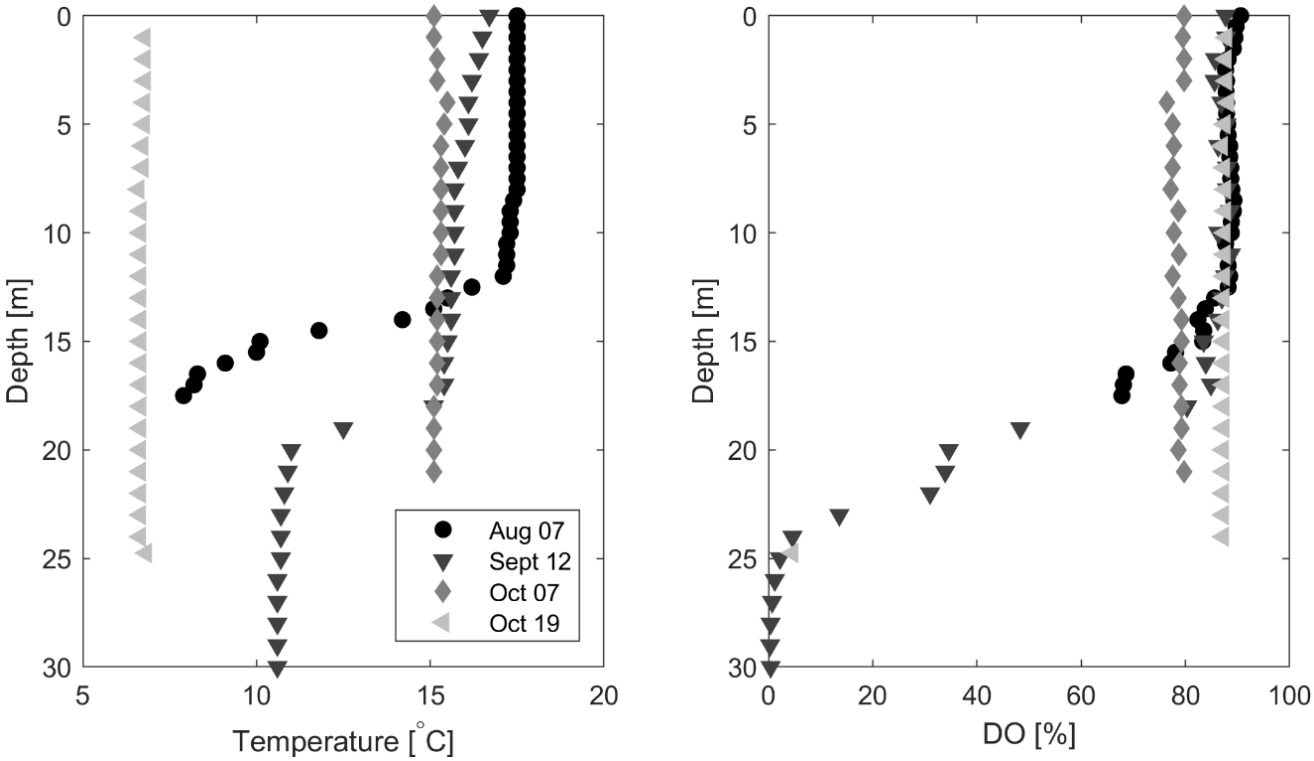

Figure 1: Temperature and dissolved oxygen (DO) profiles in Duley Lake. From 2024. Not all profiles went to the bottom.

3. Effluent Discharge Dilution and Concentration

The proposed project discharges the TSF and pit sedimentation pond waters in Duley Lake through a diffuser located at 14 m depth, 300 m from the east bank near the center of the lake. The diffuser discharges the effluent, efficiently diluting it with lake water. The maximum concentration of a pollutant in the lake is the ambient concentration in the lake plus the concentration due to the effluent discharge plume. The ambient lake concentration depends on the inflows and outflows. Near the diffuser, the effluent dilution (mixing with ambient lake water) is function of the diffuser parameters (geometry, flow rate, density) and ambient lake conditions (currents, stratification). Moving away from the diffuser, ambient lake conditions entirely control the fate of the plume. The zone where the diffuser parameters control the plume dynamics is called the near field zone (NFZ). The zone where lake ambient conditions control the plume dynamics is the far field zone (FFZ). In the FFZ, concentrations decrease to ambient lake values.

The dilution (d) of the discharged effluent is calculated as the ratio of lake water to effluent, *e.g.* a dilution of 30 means 30 l of lake water for 1 l of effluent discharged. The concentration at a certain location and time is calculated with the ambient concentration (C_a), the effluent concentration (C_e) and the dilution (d). For example, for an ambient lake concentration of 10 mg/m^3, an effluent concentration of 200 mg/m^3 and a dilution of 10, the concentration is 27.3 mg/m^3 at that location:

$$C = \frac{C_a \times d + C_e \times 1}{(d+1)} = \frac{10 \times 10 + 200 \times 1}{11} = 27.3 \qquad (1)$$

The ambient concentration of a substance in the lake depends on the inflows/outflows of the lake. More mine inflows compared to natural inflows will lead to higher ambient concentration. Therefore, the assimilative assessment is divided into two sections. The first section assesses ambient concentrations in Duley Lake. The second section assesses the dilution of effluent by the diffuser in the NFZ (effluent discharge plume dynamics). The minimum theoretical concentrations are the ambient concentrations and correspond to the average concentrations that will be observed outside of the NFZ. The maximum episodic concentrations at a distance from the diffuser are due to ambient concentrations and plume concentrations, as defined by equation 1.

3.1 Ambient Concentrations in Duley Lake

The planned amount of effluent discharged into Duley Lake is significant compared to the natural inflows (Table 1). The mine effluent accounts for 5% of the total inflows into Duley Lake. This proportion increases to 20% when the Walsh River inflow is neglected because it enters and exits the lake at the north end.

Continuous stirred tank (CST) calculations are used to estimate the average proportion of effluent in Duley Lake. CST assumes that Duley Lake is well mixed horizontally and vertically. Measurements at multiple locations in Duley Lake support the horizontal homogeneity

assumption. The vertical homogeneity assumption is supported by the fact that Duley Lake turns over and mixes completely twice a year. This 6-month time scale is less than the hydraulic residence time (around 1 year). CST calculations are carried out as follows:

$$V^{lake}\frac{\partial C^{lake}}{\partial t} = Q_{in}^{rivers}C_{in}^{rivers} + Q_{in}^{mine}C_{in}^{mine} - Q_{out}^{lake}C_{out}^{lake} \qquad (2)$$

Where V^{lake} is the lake volume (78 million m^3), C is the concentration of a particular pollutant and Q is the flow rate (in/out of Duley Lake, Figure 2). Equation 2 states that the change of ambient concentration of a pollutant (the term on the left-hand-side) is function of the inflow flow rates and concentrations. The outflow concentration is the ambient lake concentration (well mixed lake).

If the concentration of a pollutant is near 0 in the inflowing rivers, the first term on the right-hand-side can be omitted and the concentration of a pollutant will increase until the second and third terms are equal. Assuming the lake outflow is equal to the inflows from the rivers and the mine, the concentration of a pollutant in the lake (C_{out}^{lake}) will therefore converge towards:

$$C_{out}^{lake} = C_{in}^{mine}\frac{Q_{in}^{mine}}{(Q_{in}^{rivers} + Q_{in}^{mine})} \qquad (3)$$

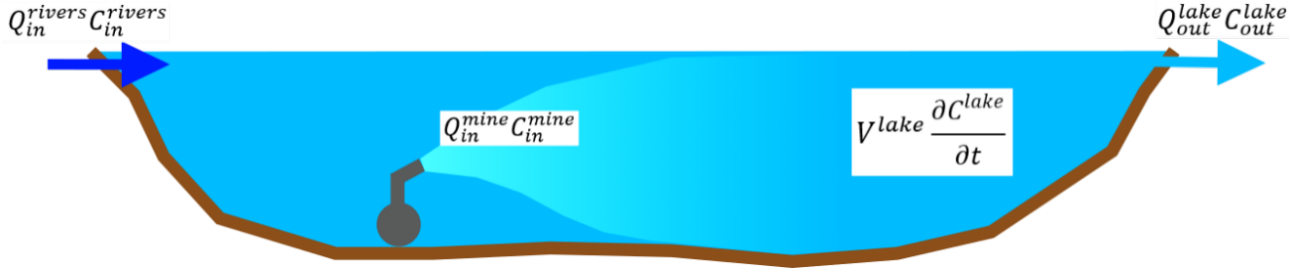

Figure 2: Schematic of the CST calculation for the ambient lake concentrations

Equation 3 shows that the average ambient concentration of a pollutant in Duley Lake depends on the mine inflow and concentration, and on the natural river inflows. For the same mine inflow concentration, the ambient concentration in Duley Lake is dictated by the ratio of mine inflow to total (mine+natural) inflow.

Using the forecasted natural and mine inflows and using a mine inflow concentration of 100%, CST calculations show that the proportion of effluent in Duley Lake will reach 10% after 1 year of operation and will settle around 21% after 20 years of operation (Figure 3). There will be seasonal fluctuations (±3%) due to more natural inflows in the spring and less natural inflows in winter. These numbers do not take into consideration the inflow from the Walsh River. If it is added, the proportion of effluent water in Duley Lake decreases between 3% and 10%, depending

on the time of the year. Without the Walsh River, this means that the minimum concentration of a pollutant in Duley Lake is 21% of the mine discharge concentration, if its concentration is 0 in natural inflows. For example, if the sulfate concentration of the mine effluent is 4.5 µg/l, and the sulfate concentration in the natural inflows is 0, the average concentration in Duley Lake will be ~0.95 µg/l after a few years of operation. If the concentration of a pollutant is non negligible in natural inflows, its concentration will be a combination of river inflows concentration (~79%) and mine inflow (~21%).

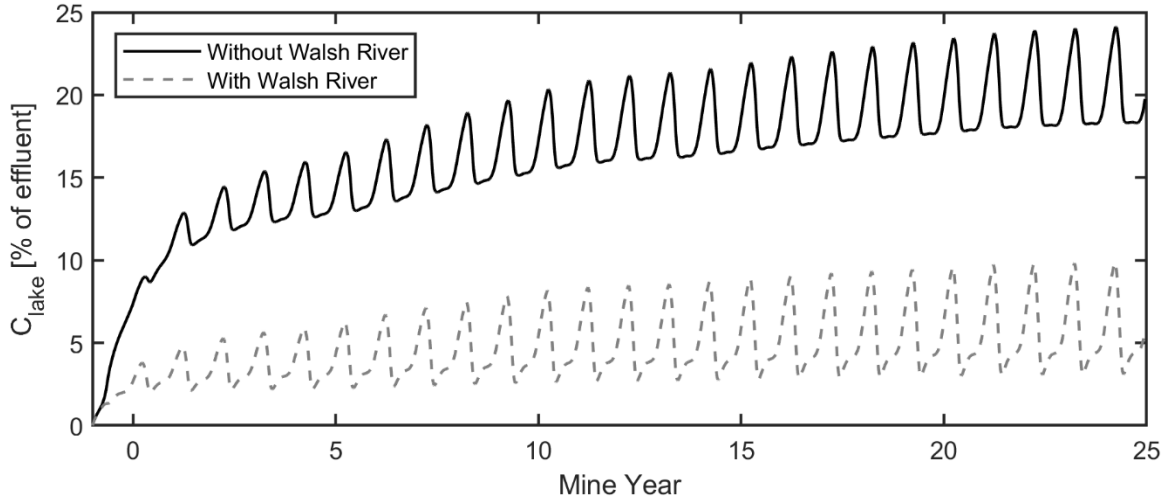

Figure 3: Average ambient fraction of effluent water in Duley Lake from CST calculations.

3.2 Effluent Plume Dynamics

In addition to the ambient lake concentration, there will be a plume of higher concentration near the diffuser (NFZ). The role of the diffuser is to mix (dilute) the effluent water efficiently with the ambient lake water.

The CORMIX software (Jirka et al. 1991) is used to calculate the dilution. The minimum dilution (at center of the effluent plume) is calculated at 100 m increments from 100 m to 1000 m from the diffuser. Mine effluent flow rates are varied from 1,000,000 m^3/month (0.39 m^3/s) to 4,500,000 m^3/month (1.74 m^3/s). Three different lake scenarios are tested:

- Spring/fall: The lake is homogeneous at a density of 4°C, the currents are 2 cm/s. The effluent is freshwater at 4°C.
- Summer: The lake is stratified with an 8 m thick epilimnion at 17°C and a hypolimnion at 7°C. The currents are 2 cm/s. The effluent is freshwater at 17°C
- Winter: The lake is ice covered (1 m thick ice) and reversely stratified with a 1 m tick epilimnion a 1°C and a hypolimnion at 4°C. The currents are 0.04 mm/s. The effluent is freshwater at 4°C.

The proposed diffuser has the following specifications:

Table 2:
Diffuser specifications

Diffuser Depth	Length	Number of ports	Port diameter	Port height	Angle between ground and port outflow
14 m	100 m	11	0.25 m	1.0 m	30°

This design is found a good compromise between size and dilution efficacy. Remotely operated control valves to open/close certain ports would improve dilution for periods of low flow rates. If needed, increasing the length of the diffuser is the more effective way of increasing dilution rates.

The minimum dilution ratios are found for the summer scenario when stratification is present (Table 3, Figure 4). The dilution rates in summer are slightly less than for winter and are a factor two less than for the spring and fall (Appendix B) because the effluent becomes trapped between the epilimnion and the hypolimnion. This is due to the mixing of the effluent with denser water at depth, resulting in the effluent plume having an intermediate density between the epilimnion and hypolimnion. If the epilimnion is, for example 5 m deep, the plume will rise to 5 m and then spread laterally between approximately 4 and 6 m depth.

Table 3:
Discharge plume dilution as function of flow rate and distance from the diffuser for the summer scenario. Flow rates in bold correspond to the mean flow rates expected in summer. Dilution values in bold are outside of the NFZ and thus controlled by mixing due to the lake dynamics; in this case currents at 2.5 cm/s

Effluent flow rate [m^3/s]	Distance from the diffuser [m]									
	100	200	300	400	500	600	700	800	900	1000
0.39	**48**	**56**	**60**	**63**	**66**	**69**	**71**	**73**	**75**	**77**
0.58	36	38	**40**	**43**	**45**	**46**	**47**	**48**	**49**	**51**
0.77	33	35	38	40	42	45	47	49	**51**	**52**

1.35	27	31	34	37	39	42	44	46	48	50
1.54	27	31	34	36	40	42	44	46	47	50
1.74	27	30	33	37	39	41	43	45	46	49

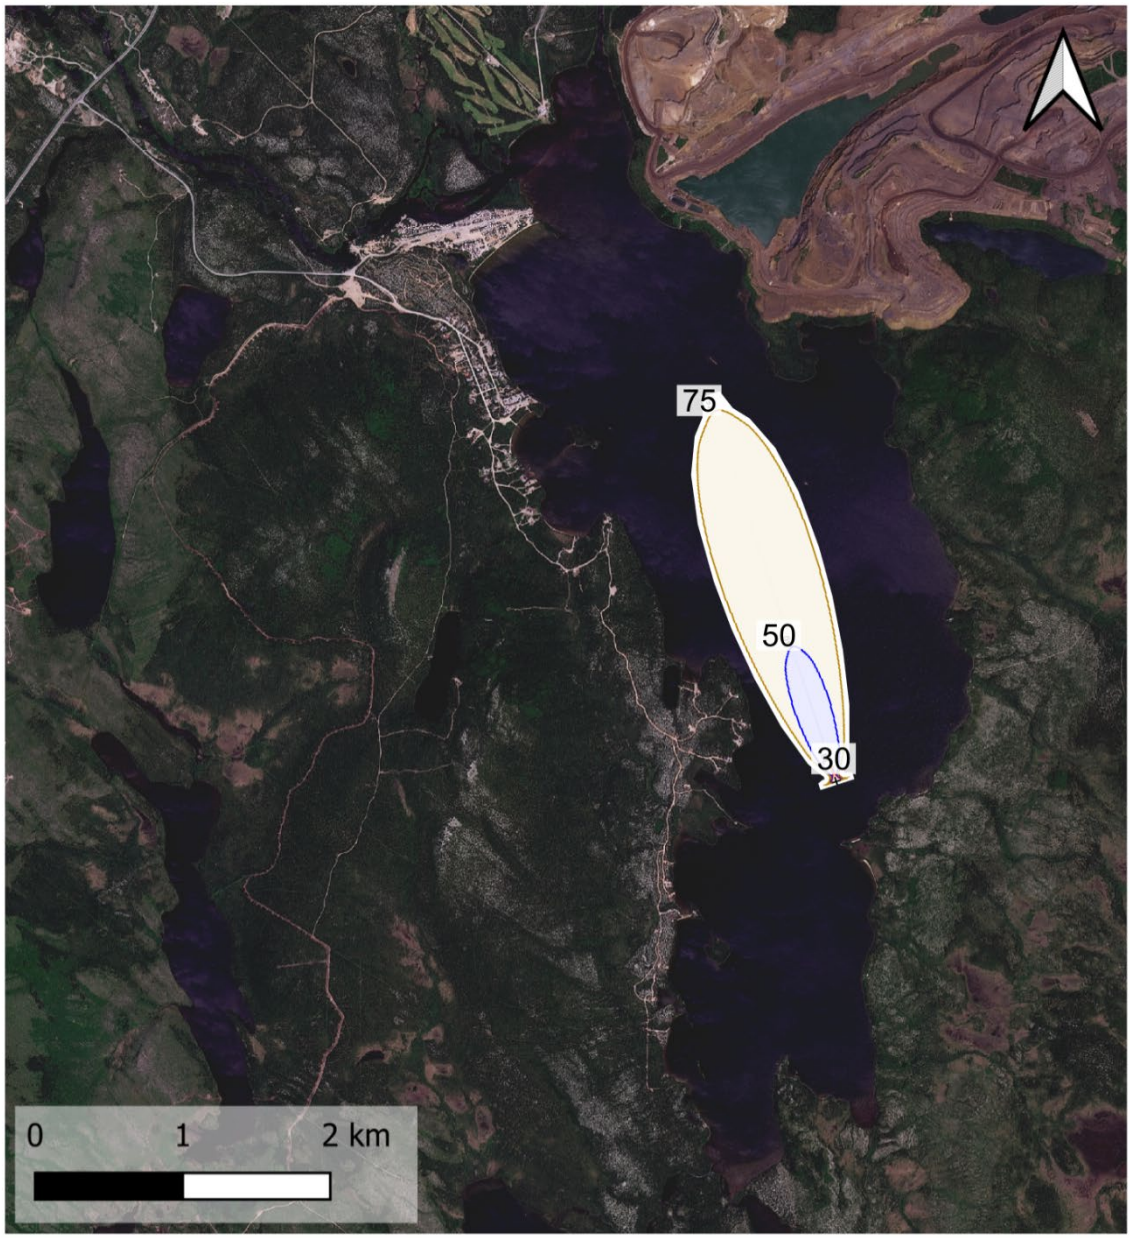

Figure 4: Discharge plume dilution footprint from the CORMIX simulation for the summer scenario with a discharge of 1.16 m^3/s (3,000,000 m^3/month).

3.3 Ambient and Plume Concentrations

The CORMIX simulations show that the proposed diffuser efficiently mixes the effluent with ambient lake water. However, the minimum concentration of a pollutant achievable is the ambient lake concentration, which will be around 21% of the effluent concentration. To illustrate this point, the maximum concentration of sulfate (discharge plume+ambient) is calculated using the summer dilution values (Table 3), an effluent concentration of 4.5 µg/l and a natural inflow concentration of 0. The results (Table 4) show that the concentration exceeds the ambient concentration

(0.95 µg/l) by a maximum of 11% at 100 m from the diffuser for the maximum flow rate, implying the proposed diffuser is sufficiently efficient.

Table 4:
Maximum concentration (µg/l) of sulfate near the diffuser for the summer scenario. These calculations assume an ambient sulfate concentration of 0.95 µg/l, which is 21% of the discharge concentration (4.5 µg/l).

Effluent flow rate [m^3/s]	Distance from the diffuser [m]									
	100	200	300	400	500	600	700	800	900	1000
0.39	1.018	1.007	1.003	1.001	0.998	0.996	0.994	0.993	0.992	0.991
0.58	1.041	1.036	1.032	1.026	1.022	1.021	1.019	1.018	1.016	1.013
0.77	1.050	1.044	1.036	1.032	1.028	1.022	1.019	1.016	1.013	1.012
0.96	1.060	1.047	1.041	1.034	1.030	1.026	1.021	1.018	1.015	1.012
1.16	1.060	1.050	1.044	1.036	1.032	1.028	1.022	1.019	1.016	1.013
1.35	1.072	1.056	1.047	1.039	1.034	1.028	1.024	1.021	1.018	1.015
1.54	1.072	1.056	1.047	1.041	1.032	1.028	1.024	1.021	1.019	1.015
1.74	1.072	1.060	1.050	1.039	1.034	1.030	1.026	1.022	1.021	1.016

The CST calculations assume a fully mixed lake. This is correct on long time scales (>1 year) and as a lake average. However, at a particular location and on shorter time scales, lake dynamics will lead to fluctuations around the CST values. During spring and fall turnover, the lake will be homogeneous in the vertical and the wind should efficiently mix the lake horizontally, leading to a well mixed lake and ambient concentration near the CST estimate everywhere except very near the plume (Figure 5). During summer, it is expected that the effluent will settle near the base of the epilimnion. This will lead to an accumulation of effluent water and higher ambient concentration at this depth. However, as the thermocline deepens, this higher concentration water will become part of the epilimnion and mix vertically more efficiently. The lake will become fully mixed in the fall when summer stratification breaks down. In winter, the reversed stratification under the ice cover should confine the effluent to below ~2 m from the surface (~1 m below the ice). Assuming inflows are near the freezing point, they will be confined to the upper water column and poorly renew the water where the effluent will mix. This will lead to higher ambient concentration below ~2 m. Moreover, the very slow currents expected under ice will lead to horizontal differences in concentrations across the lake because of limited horizontal mixing.

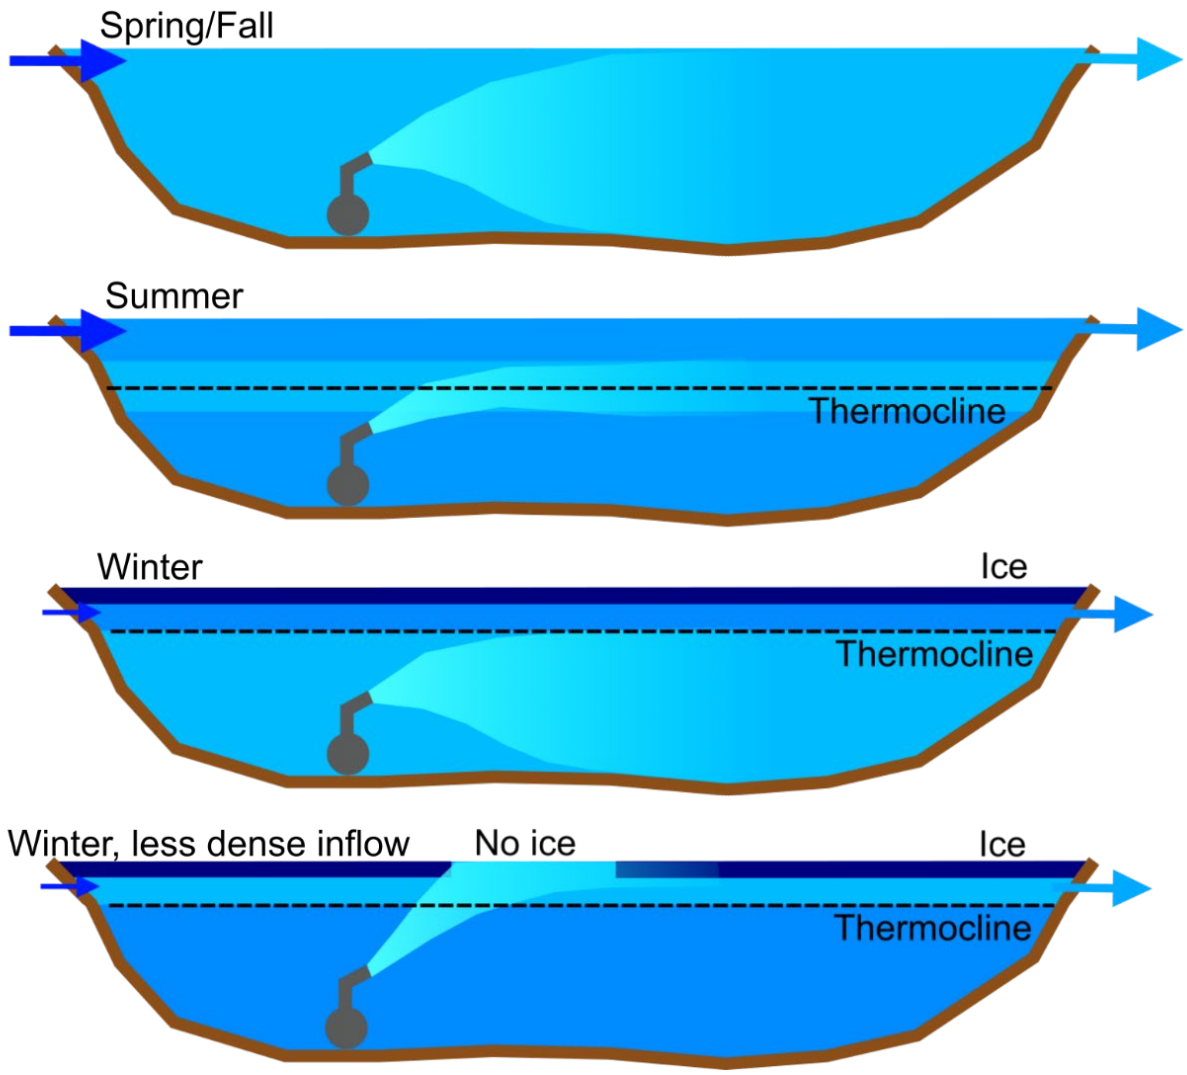

Figure 5: Schematic of seasonal processes impacting the vertical distribution of the discharged effluent water. The bottom panel illustrates the potential loss of ice cover in the case where the density of the effluent is significantly less than the density of lake water.

4. Limitations, Additional Concerns and Recommendations

- It is clear that the assimilative capacity of Duley Lake is dictated by ambient lake concentrations. The calculated ambient effluent concentration of ~21% using CST calculation is preliminary. The largest unknown is the influence of the Walsh River, which could potentially decrease the ambient effluent concentration between 3% and 10%. In situ-observations and dye experiments may be conducted to address this uncertainty.

- CST calculations assume a well mixed lake. There will be concentration fluctuations around the results given by CST calculations. Three-dimensional modelling of Duley Lake is recommended to estimate the amplitude and frequency of the concentration fluctuations.
- The density of the mine effluent discharged into Duley Lake is extremely important with regards to the dilution of the diffuser plume. CORMIX simulations with a discharge denser than the lake water by more than 0.1 kg/m^3 show the plume will sink. This might lead to effluent accumulation in the deeper region of the lake near the diffuser. Moreover, if the discharge is more than 0.2 kg/m^3, it may lead to sediment resuspension because of the outflow jet running along the lake bottom. A denser discharge may be caused by increased total suspended sediments and/or temperature differences. Inversely, if the effluent is less dense than the ambient lake water, it may rise to the surface. This may result in higher effluent concentration at the surface and the loss of ice cover in winter (or fragile ice). Pumping water from as deep as possible in the sedimentation pond (avoiding sediments) is recommended to limit the density (temperature) difference with lake water. Monitoring the density of the lake and the effluent is recommended.
- The currents in the lake are not fixed, the discharge plume will move around in all seasons. The discharge plumes modelled with CORMIX are steady state, *i.e*. the ambient current has a fixed direction and magnitude. A moving plume will result in peak concentrations (minimum dilution) that are less (more) than the results presented. Therefore, the results in Table 3,5 and 6 can be considered as the worst episodic case scenario*, i.e.* if the lake currents are unchanged for a long period of time. Current observations in Duley Lake are recommended to reduce the uncertainties on the water velocities. As the current values used for the discharge plume modelling were conservative (small velocities), observations would likely allow to increase these values, thereby increasing the plume dilution rates obtained.
- CORMIX simulations were carried out without lateral boundaries. If the lake currents carry the discharge plume towards the lake shore southeast of the diffuser, the discharge plume will reflect on the boundary and higher peak episodic concentrations might occur.
- The effluent discharge rates (1.0 Mm^3/month to 4.5 Mm^3/month) used for the discharge plume modelling represent monthly mean values. Hourly/daily higher/lower values are possible in the case of floods/droughts.

5. Conclusion

Because of the small volume of Duley Lake and the large volume of mine effluent compared to the natural inflows, the assimilative capacity of the lake is dictated by the ambient concentrations. The average ambient concentration of a pollutant discharged into Duley Lake is around 21% of

the effluent concentration (assuming the concentration in natural inflows is negligible). If the concentration of a pollutant is 100 µg/l in the effluent discharged into Duley Lake, the minimum possible ambient concentration in the lake is ~21 µg/l. The magnitude of the temporal and spatial fluctuations around the average ambient lake concentration is uncertain. More observations and three-dimensional modelling of the lake are recommended to quantify these fluctuations. The ambient concentration estimates could be decreased providing in-situ observations allowing the quantification of the impact of the Walsh River on Duley Lake.

The proposed diffuser efficiently mixes the effluent plume with ambient lake water, decreasing pollutant concentration to within 11% of the ambient lake concentration within 100 m from the diffuser. The density of the effluent is however important to monitor in order to avoid accumulation at the bottom of the lake or surfacing and possible weakening of the ice cover.

Appendix A:

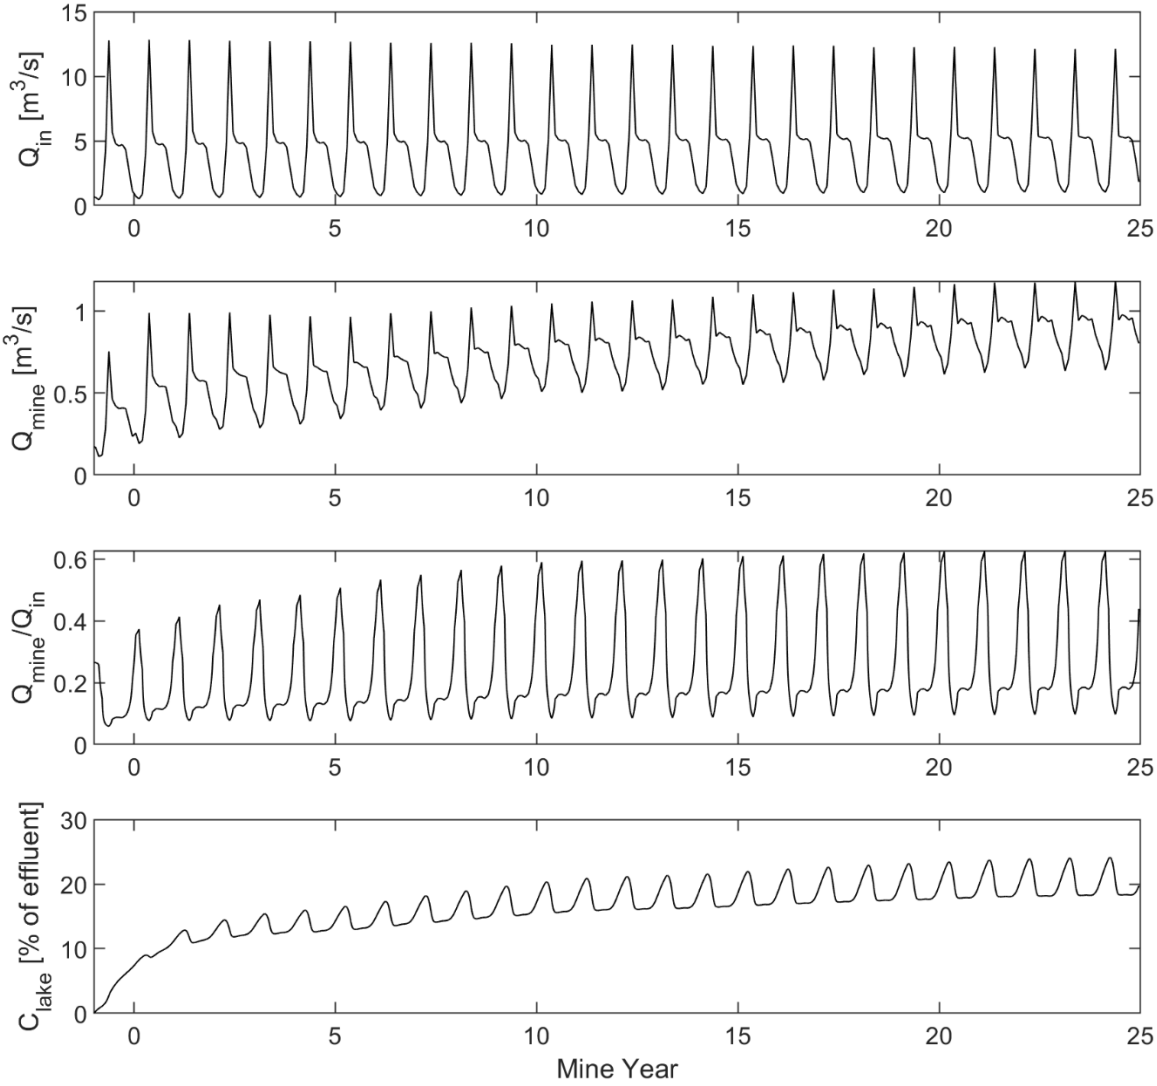

Figure A-1: Fraction of water in Duley Lake that is from mine effluent. The average concentration of effluent water in Duley Lake will be above 10% after 1 year of operation and will settle around 21%. These results are neglecting the inflow from the Walsh River.

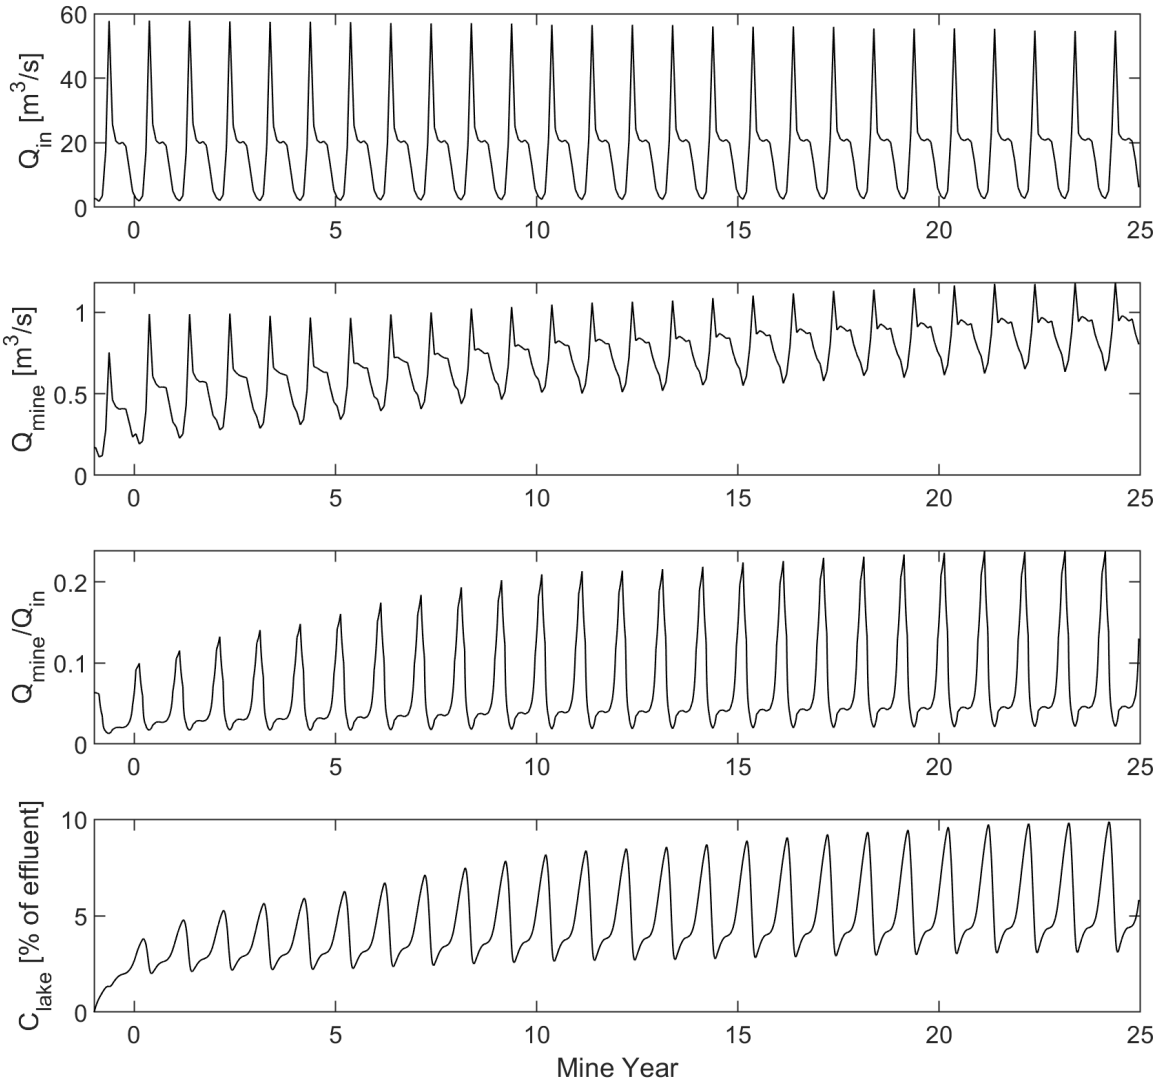

Figure A-2: Fraction of effluent water in Duley Lake from CST calculation. These results include the inflow of the Walsh River.

Appendix B:

Spring/Fall Scenario

Table 3 shows the dilution rates expected in spring and fall when the water column has a homogeneous density and the effluent has a similar density. Because densities are the same, the effluent mixes over the whole water column height.

Table : B-1
Discharge plume dilution as function of flow rate and distance from the diffuser for the spring/fall scenario. Flow rates in bold correspond to the mean flow rates expected in spring/fall. Dilution values in bold are outside of the NFZ and thus controlled by mixing due to the lake dynamics; in this case currents at 2.5 cm/s.

Winter

Table 6 shows the dilution rates expected during the period when Duley Lake is ice-covered. The dilution rates are similar to the summer stratified scenario. Most of the dilution occurs rapidly near the diffuser. The very slow currents (0.04 mm/s) result in minimal dilution once the plume exits the vicinity of the diffuser.

It is important to note that the effluent temperature for this scenario is 4°C, which is the lake water temperature from the bottom to approximately 1 m below the ice cover. If the effluent water is colder than 4°C, which is possible if it is pumped from near the surface of the sedimentation pond, the effluent water will be less dense than the lake water and will rise to near the surface under the ice. This will result in significantly less dilution and might lead to the loss of ice cover near the diffuser as there will be a plume of water rising to the surface.

Table B-2:
Discharge plume dilution as function of flow rate and distance from the diffuser for the winter scenario. Flow rates in bold correspond to the mean flow rates expected in winter.
