ABSTRACT

This report provides whole-rock geochemical data from the Julianne Lake iron ore deposit, western Labrador ((NTS map area 23G/02), and forms part of a multiyear study investigating the geology, alteration and structural evolution of the deposit (Conliffe, 2013). In total, 338 drillcore samples and 26 outcrop samples were analyzed, and full geochemical data are provided for major elements, trace elements and rare-earth elements. In addition, sample locations, sample descriptions and a brief description of the major results and trends are included.

PROJECT OVERVIEW

The Julianne Lake iron ore deposit is located *ca.* 32 km by road, north of the town of Wabush, on a peninsula between Wabush Lake to the west and Julianne Lake to the east (NTS map area 23G/02; Figure 1). The deposit was first identified by the Newfoundland and Labrador Company (Nalco) in 1953, and is one of the largest undeveloped iron ore deposits in the region. In 1975, the rights to the deposit reverted to the crown under the Julianne Lake Deposit (Reversion Act) 1975 and the property was made an Exempt Mineral Land (EML). The provincial government conducted a drilling and trenching program and preliminary metallurgical study in 2010, to define the deposit to the level of NI 43-101 compliant indicated and measured resources, establish a reliable 3-D geological model and generate preliminary pit designs. The results of this study was released in October 2012, with a non NI-43-101 compliant geological resource estimate of 1166 Mt grading approximately 33% Fe, including a measured and indicated resource of 867 Mt at 33.7% Fe (Coates *et al.* 2012).

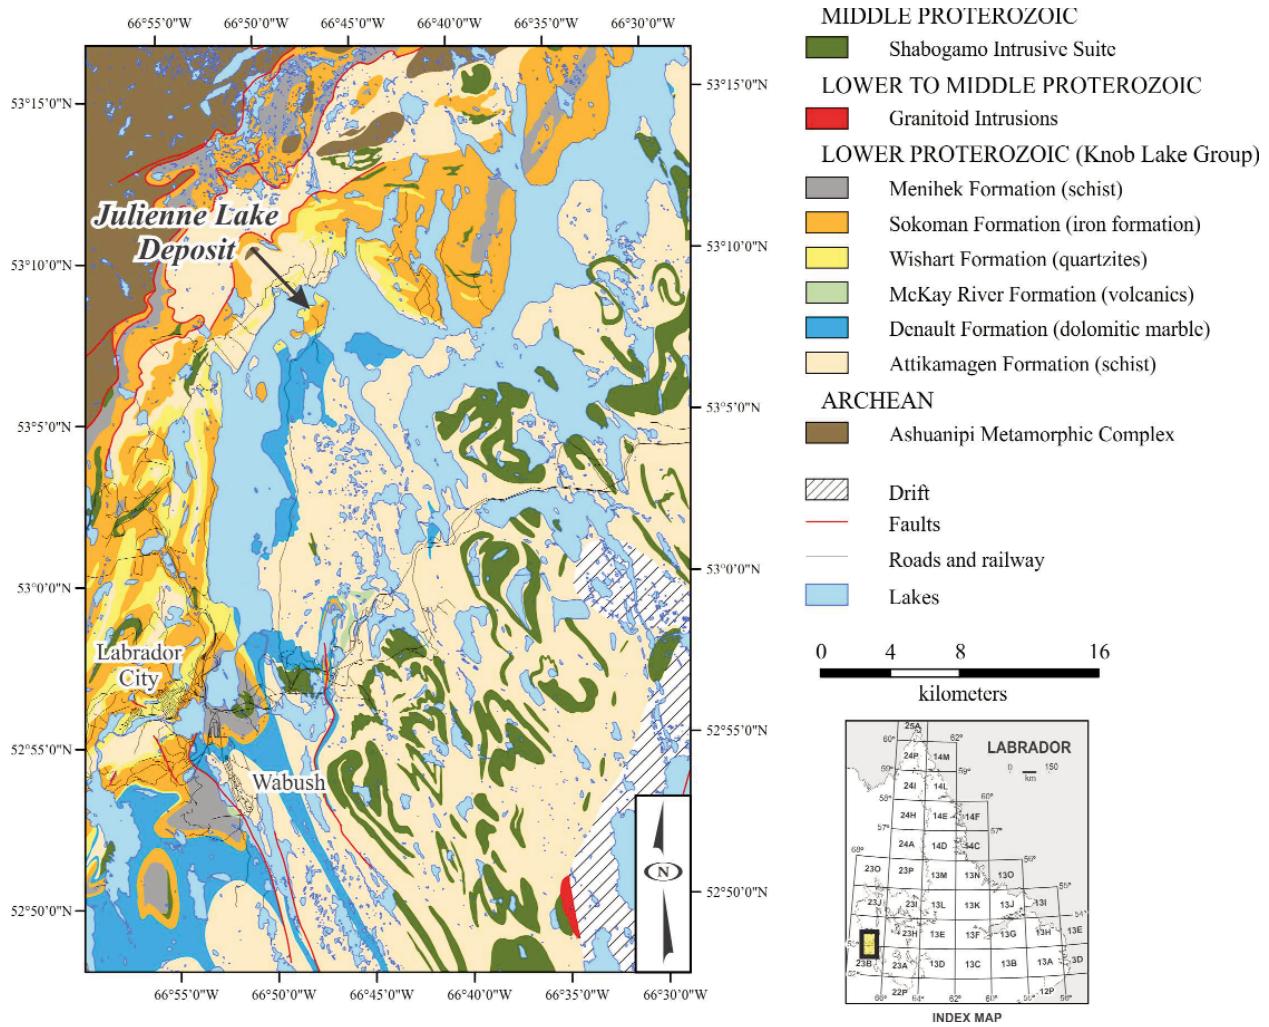

Figure 1: Regional geological map of the area around the Julianne Lake iron ore deposit (after Rivers and Massey, 1985).

In 2012, the Geological Survey of Newfoundland and Labrador (GSNL) initiated a study aimed at understanding the geology, alteration and structural evolution of the Julianne Lake iron ore deposit, and to compare it with other iron ore deposits in the Labrador City/Wabush area. Fieldwork in 2012 included mapping and sampling of outcrops and exposed trenches at Julianne Lake. In addition, 12 diamond-drill holes from the 2010 drilling program were logged and samples were collected for petrographic and geochemical analysis. The preliminary results of this work were presented in Conliffe (2013), and five main rock types were identified at the Julianne Lake iron ore deposit. These are:

- *Quartz-specularite Schist (QS)*: This unit makes up > 95% of the total thickness of iron formation in the logged drillholes. It consists of semi-massive to banded iron formation (quartz + specular hematite ± martite) and is commonly leached and friable (altered to earthy red hematite and goethite).
- *Mn-rich Iron Formation (MnIF)*: Pyrolusite-bearing iron formation accounts for < 2.5% of the total thickness of iron formation in the logged drillholes.
- *Lean White Quartzite (LWQ)*: This ferruginous white quartzite (quartz >> specular hematite) makes < 3% of the total thickness of iron formation in the logged drillholes.
- *Lower Iron Formation (LIF)*: This distinctive unit has been recorded at the base of the iron formation in all drillholes which penetrate the iron formation. It is strongly altered and brecciated and consists of red hematite, quartz, goethite and iron silicates, with rare specularite bands and euhedral garnets pseudomorphs.
- *Wishart Formation Quartzite (WQ)*: The Wishart Formation quartzite defines the footwall contact of deposit, and varies in composition from pure white quartzite to micaceous and weakly ferruginous quartzite.

This open file data release consists of whole-rock geochemical data from samples collected during the 2012 field season. In total, 338 drillcore samples and 26 outcrop samples were analyzed. The appendices to this release include sample locations, sample descriptions and major-element, trace-element and rare-earth-element (REE) data. A brief description of the major results and trends is included below; there is no additional discussion on the economic or geological significance of these trends. Further details on the geology of the Julianne Lake iron ore deposit are described in Conliffe (2013).

METHODS

Drillcore samples were collected from 11 diamond-drill holes. The location of the diamond-drill holes is documented in Appendix A, and the location and brief description of each sample is included in Appendix B. Sample intervals range in length from 5 cm to 1.25 m, with most of sample intervals ranging from 10–30 cm. Samples were selected on a semi-random basis, with care taken to collect representative samples from the main rock types in each diamond-drill hole. In addition, a series of samples were collected from outcrops and exposed trenches at the Julianne Lake iron ore deposit (sample locations and descriptions in Appendix C).

All analyses were carried out at the GSNL laboratory in St. John's and analytical methods are described in Table 1. Analytical duplicates were inserted at a frequency of one in 20, with the

Table 1: Analytical methods for geochemical analysis.

Analysis	Method	Preparation/Digestion
SiO ₂ , Al ₂ O ₃ , Fe ₂ O ₃ , MgO, CaO, Na ₂ O, K ₂ O, TiO ₂ , MnO, P ₂ O ₅ , Cr, Zr, Ba	Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES-FUS)	Lithium Tetraborate Fusion
Be, Cu, Li, Mn, Ni, Pb, Rb, Sc, Ti, Zn	Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES)	HF-HCl-HNO ₃ -HClO ₄ (total digestion)
V, Co, Ga, Ge, As, Sr, Y, Nb, Mo, In, Sn, Cs, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, Hf, Ta, W, Tl, Bi, Th, U	Inductively Coupled Plasma Mass Spectrometry (ICP-MS-FUS)	Lithium Tetraborate Fusion
LOI	Gravimetric (Grav)	None

duplicate selected at random. In addition, a selection of reference standards was analyzed, also at a frequency of one in 20. For ICP-OES-FUS (major element) and ICP-MS-FUS (trace element) standards were supplied by the Canadian Certified Reference Materials Project (SCH-1), the United States Geological Survey (AGV-1, BHVO-1, BIR-1, G-2, MAG-1, QLO-1, RGM-1, SDC-1, STM-1, W-2) and the Association Nationale de la Recherche Technique, Paris (DR-N). Two standards were used for ICP-OES-FUS (trace elements) analysis, supplied by the Canadian Certified Reference Materials Project (SY-4, WGB-1). The raw, unprocessed data from duplicates and standards is included in Appendices F, G and H, and can be used by the reader to assess accuracy and precision.

RESULTS

The major-element, trace-element and REE compositions of the main rock types at Julienne Lake are included in Appendices C and D. The average and standard deviation for each rock type is shown in Table 2 (half the detection limit is used for values below detection limit), and a brief description of these results is given below.

Quartz Specularite Schist (QS)

The SiO₂ and Fe₂O₃ are the dominant major elements in all QS samples, with SiO₂ + Fe₂O₃ contents of > 90 wt. % (Figure 2). The Fe₂O₃ contents range from < 10% to > 95 wt. %, with the majority of samples ranging from 36 to 67 wt. % Fe₂O₃ (25.5 to 46.9 wt. % Fe). This variation likely reflects sample bias, with some quartz-rich and hematite-rich QS samples collected for analysis. All other major element contents are low, generally less than 0.5 wt. % (Figure 3; Table 2). When compared to geochemistry from average unmetamorphosed iron formation in the Schefferville area (Conliffe, 2013, unpublished data), QS samples from Julienne Lake are moderately to strongly depleted in mobile elements (MnO, MgO and CaO) and weakly enriched in Al₂O₃.

Table 2: Summary statistics for major element, trace element and REE content of main rock types.

For element values below detection limit, averages were calculated for half of the detection limit.

¹ Average composition of 16 iron formation samples from the Schefferville area (Conliffe, 2013, unpublished data). ² Average composition of three Ruth Formation shale samples from the Schefferville area (Conliffe, 2013, unpublished data).

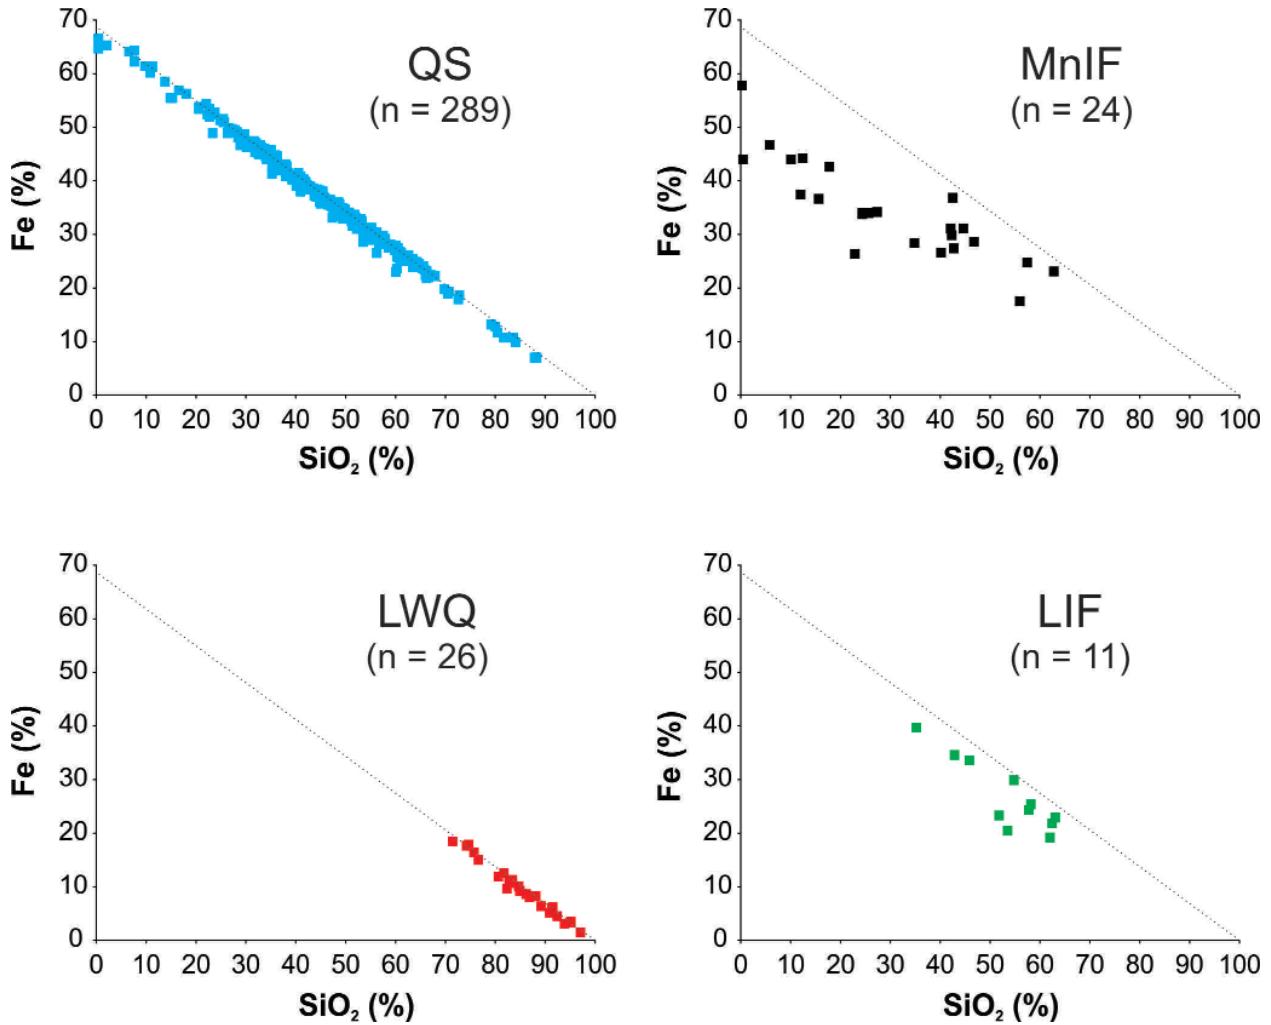

Figure 2: Bivariate plots of SiO_2 vs. total Fe. Dashed line illustrates a composition of pure SiO_2 and Fe_2O_3 .

and TiO_2 (Figure 4). The LOI ranges from 0.07 to 5.09 wt. %, with higher values corresponding to samples with higher goethite or carbonate contents.

The trace-element contents are generally low (<50 ppm), but some samples are enriched (>100 ppm) in selected trace elements *e.g.*, Ba, V, Ni, Zn, and Y. These anomalous values are attributed to residual enrichment and/or chemical weathering and no systematic variation in trace element compositions was recorded. The distribution of selected trace elements is shown in Figure 4, normalized against average iron formation composition in the Schefferville area (Conliffe, 2013, unpublished data). These data all trace elements have similar or slightly depleted concentrations in QS compared to the unmetamorphosed iron formation. However, due to the low trace-element content of analyzed samples and the parent iron formation, further interpretation is difficult.

The total REE contents (Σ REE) of QS samples are variable (ranging from 0.80 to 191.11 ppm), with most samples having low Σ REE of < 50 ppm. The REE data are normalized to the average value of post-Archean Australian shale (PAAS). The distribution of REE is also highly variable (Figure 5), with some samples strongly depleted in LREE ($La/Yb_{PAASN} < 0.2$) and others enriched

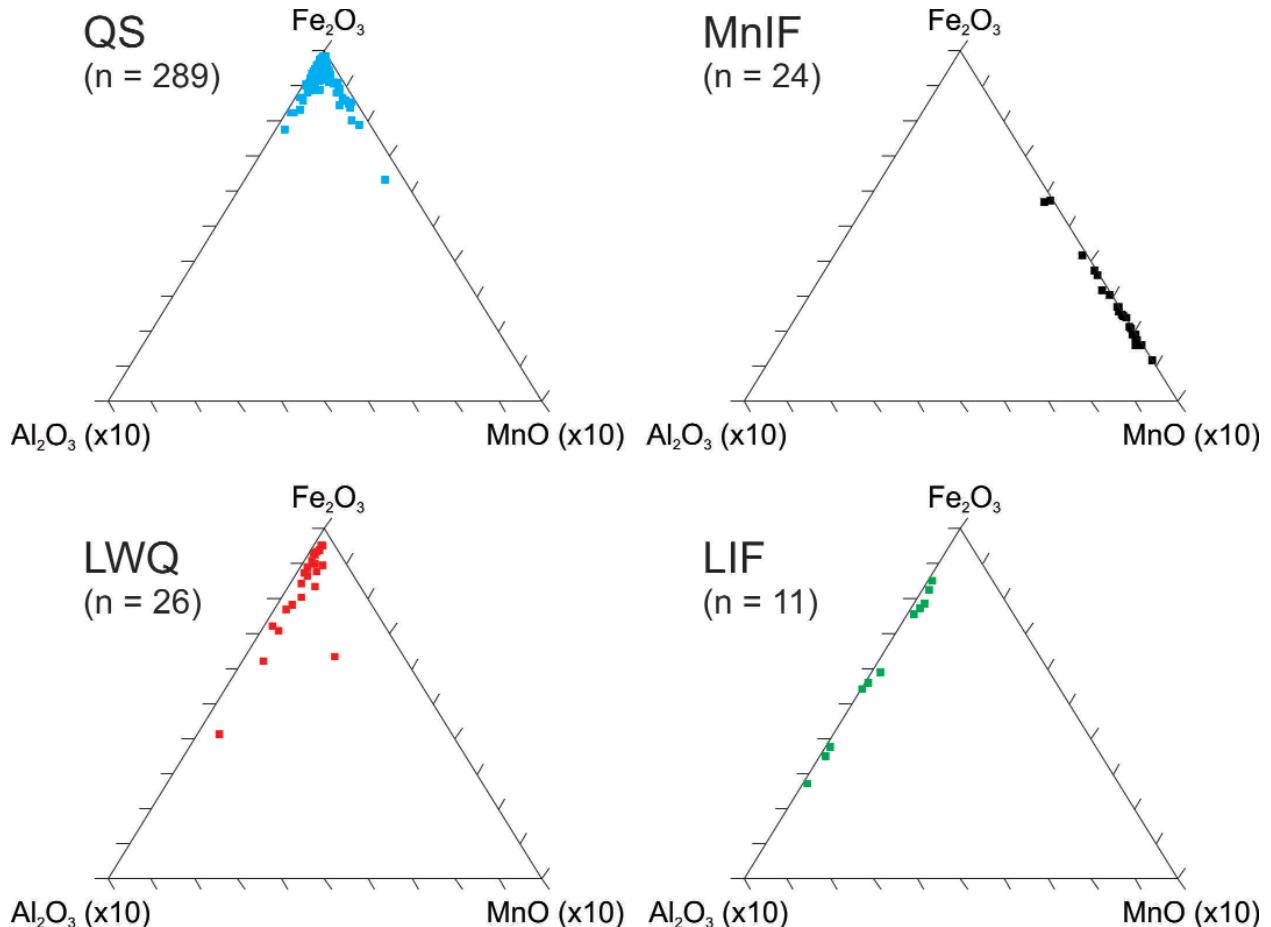

Figure 3: $Fe_2O_3 - Al_2O_3$ ($\times 10$) – MnO ($\times 10$) triangular plot showing variations in major element composition between the main rock types.

in LREE ($La/Yb_{PAASN} > 2$). Such a wide range in La/Yb ratios is unlikely to be related to primary lithological values, and is instead attributed to mobilization of LREE during later chemical weathering. Also, the QS samples have a consistent positive Eu_{PAASN} anomaly ($Eu/Eu^* = 1.36 \pm 0.26$).

Mn-rich Iron Formation (MnIF)

The Mn-rich Iron Formation is characterized by MnO contents of > 2 wt. %, with values ranging from 2.39 to 29.65 wt. %. Other major element contents are similar to QS, with the dominant elements SiO_2 and Fe_2O_3 ($SiO_2 + Fe_2O_3 = 60.4$ to 95.6 wt. %; Figure 2) and normalized plots showing strong depletion in MgO and CaO and weak enrichment in Al_2O_3 (Figure 4). These plots also show weak enrichment in Na_2O and K_2O but this is attributable to the low Na_2O and K_2O content of the parent iron formation (< 0.03 wt. %).

Trace-element data show that the MnIF samples are moderately to strongly enriched in large ion-lithophile elements (LILE), particularly Ba, Sr and Pb (Figure 4). These elements are usually mobile during fluid-rock interactions. Other trace-element contents are similar to QS samples. The REE data show that all MnIF samples are enriched in LREE ($La/Yb_{PAASN} > 1$) and have positive Eu anomalies (Figure 5).

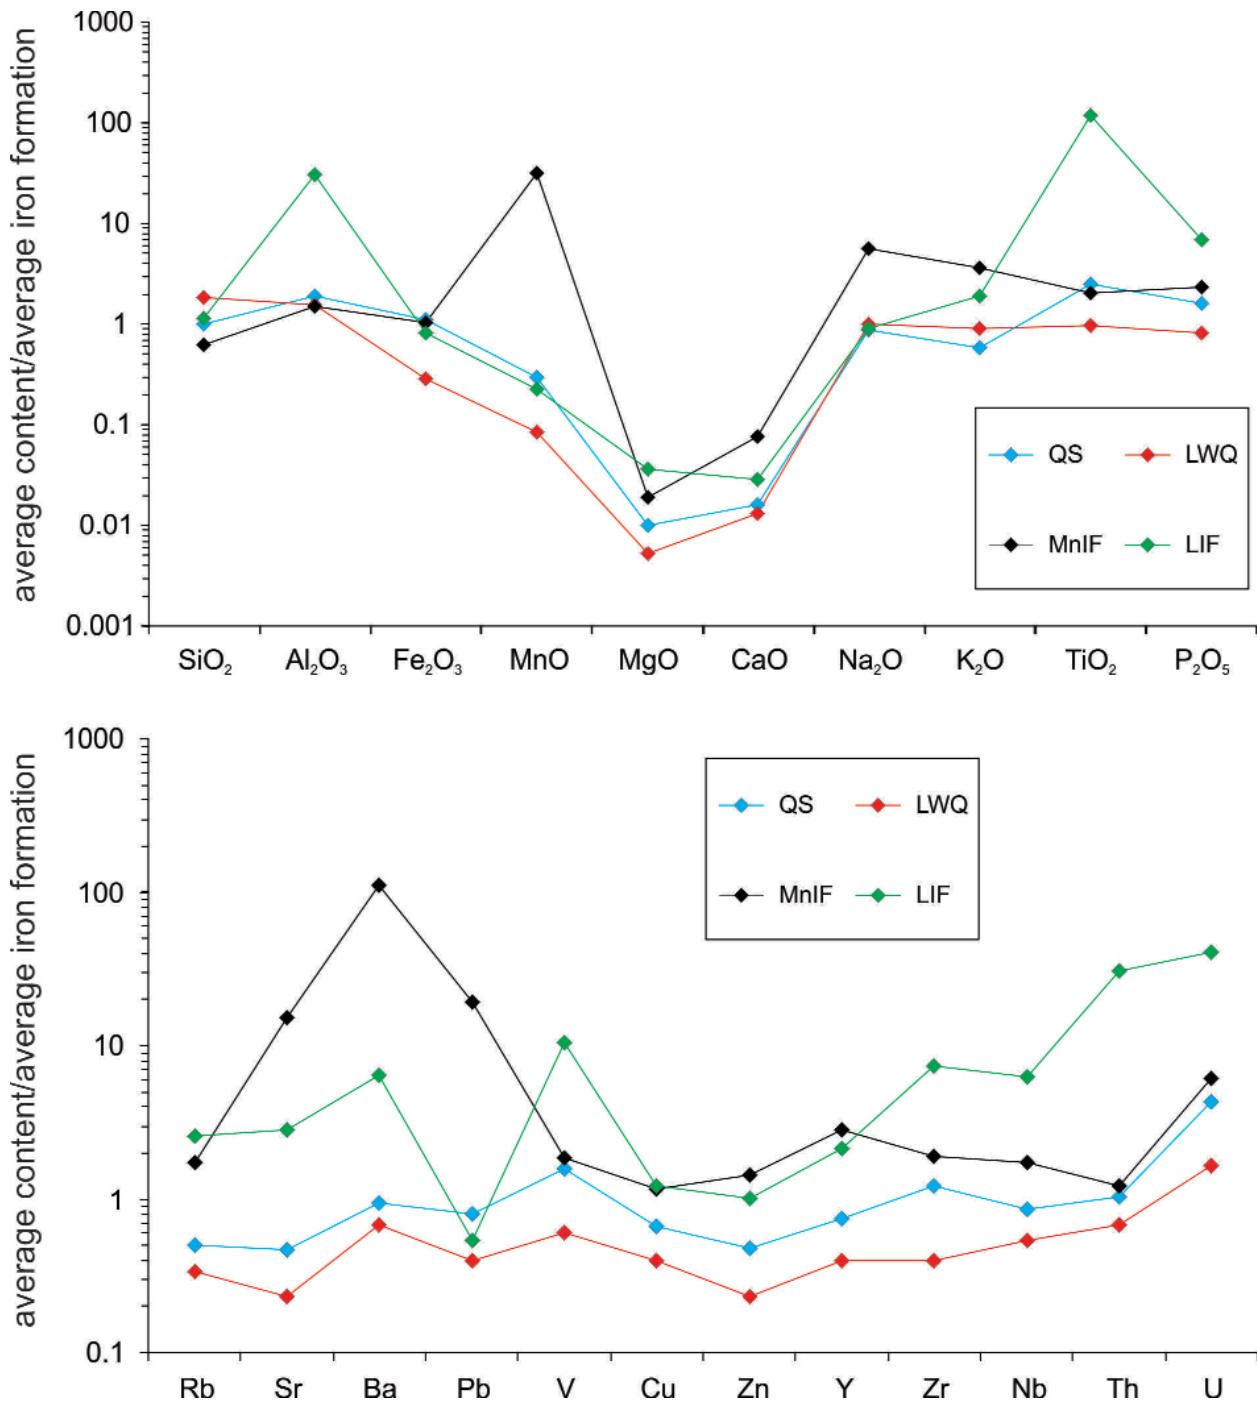

Figure 4: Major and minor element composition of main rock types, normalized against average iron formation composition from Schefferville area (Conliffe, 2013, unpublished data).

Lean White Quartzite (LWQ)

The LWQ is distinguished from QS by its high SiO_2 (71.5 to 97.1 wt. %) and low Fe_2O_3 (2.03 to 26.47 wt. %) contents (Figure 2). Other major element contents are similar to QS, with normalized values showing moderate to strong depletion in MnO , MgO and CaO and weak enrichment in Al_2O_3 (Figure 4). Trace-element contents are low (< 50 ppm) and generally weakly to moder-

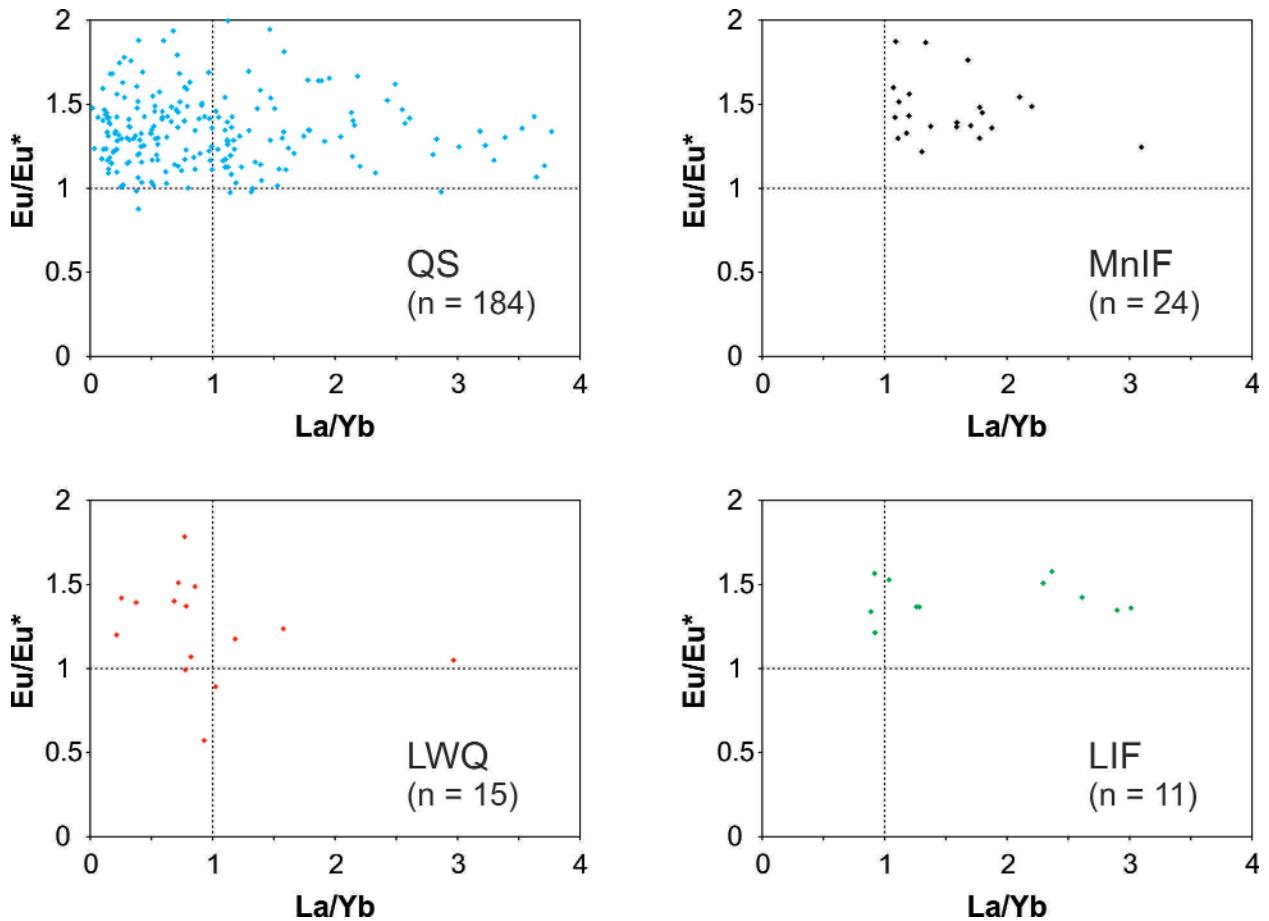

Figure 5: Bivariate plots of $\text{La/Yb}_{\text{PAASN}}$ vs. $\text{Eu/Eu}^*_{\text{PAASN}}$. All data normalized to post-Archean Australian shale (McLennan, 1989). $\text{Eu/Eu}^* = \text{Eu}_{\text{PAASN}} / ((\text{Sm}_{\text{PAASN}} + \text{Gd}_{\text{PAASN}}) / 2)$.

ately depleted compared to the parent BIF (Figure 4). The ΣREE content is very low (< 39 ppm) and samples are generally depleted in LREE ($\text{La/Yb}_{\text{PAASN}} < 1$) with positive Eu anomalies (Figure 5).

Lower Iron Formation (LIF)

The LIF samples have high Al_2O_3 (0.72 to 7.94 wt. %) and TiO_2 (0.11 to 1.55 wt. %) contents when compared to all other iron formation rock types (Figures 3, 4; Table 2). These elements are considered to be highly immobile during all fluid-rock interactions, and such high values indicate either significant volume loss or variations in the original composition of the original sedimentary rock. Similar high Al_2O_3 and TiO_2 contents have been recorded from the Ruth Formation shale in the Schefferville area (Table 2) and due to their similar stratigraphic position (at the base of the iron formation) the LIF is interpreted as a metamorphic equivalent of the Ruth Formation. The balance of the major elements in the LIF predominantly consists of SiO_2 and Fe_2O_3 ($\text{SiO}_2 + \text{Fe}_2\text{O}_3 = 83.1$ to 98 wt. %; Figure 2) with all other major elements < 0.6 wt. %.

Trace-element contents are generally higher in the LIF than all other iron formation rock types. With the exception of Pb all trace elements are weakly to strongly enriched compared to

average iron formation (Figure 4). In particular, the high-field-strength elements (HFSE) such as Y, Zr, Nb, Th and U are enriched by factors of 2.16 to 40.29. Like Al_2O_3 and TiO_2 these elements are considered immobile, and the high values recorded in the LIF are similar to HFSE contents of Ruth Formation shales in the Schefferville area (Table 2). The REE data indicate that LIF samples can be subdivided into two populations based on their $\text{La}/\text{Yb}_{\text{PAASN}}$ ratios (Figure 5). This is not related to sample location or any systematic variation in major or trace elements, and may be related to varying degrees of chemical weathering.

Wishart Formation Quartzite (WQ)

The Wishart Formation quartzite has high SiO_2 content (74.3 to 98.6 wt. %) and relatively low Fe_2O_3 content (0.1 to 4.5 wt. %). In addition, WQ samples have variable Al_2O_3 (0.3 to 13.6 wt. %) and K_2O (0.1 to 6 wt. %), reflecting the high muscovite composition of some samples. Trace-elements contents are generally low (< 100 ppm) with the exception of Ba (up to 1260 ppm) and Zr (up to 608 ppm). The REE data show that WQ samples are enriched in LREE ($\text{La}/\text{Yb}_{\text{PAASN}} > 1.5$). In contrast to the iron formation samples, most WQ samples have negative Eu anomalies ($\text{Eu}/\text{Eu}^* < 1$), consistent with the non-hydrothermal origin of the Wishart Formation quartzite.

ACKNOWLEDGEMENTS

Sample preparation and geochemical analyses were carried out under the supervision of Chris Finch of the GSNL Geochemistry Laboratory. Garrett Martin provided able assistance during the 2012 field season and Wayne Tuttle is thanked for his excellent logistical support in Goose Bay. The staff of the Mineral Development Division are thanked for providing information on the 2010 exploration program and for assistance during an initial field visit. In particular, John Clarke is thanked for numerous insightful discussions on the geology of the Julienne Lake iron ore deposit. Andrew Kerr provided a thoughtful review of an early version of this document.
