## **ABSTRACT**

*This open file reports the results of geochemical analyses of 206 B-, BC- and C-horizon till samples obtained in a regional sampling program over the subcrop of the Glover Group in western Newfoundland. The area sampled (using an approximate 1 to 3.5 km space grid) includes all of Glover Island, and the area lying between Grand Lake, Little Grand Lake and the Topsail Hills. Estimation of data quality was performed by examining the results of analyses from duplicate samples collected from the same site obtained in the field, and from duplicates generated by re-analysis of the same sample in the laboratory.*

*Till geochemistry has identified several possible targets for exploration, including gold mineralization on Glover Island, in areas with no previous known gold showings; possible gold mineralization associated with arsenic between Little Grand Lake and Grand Lake; nickel on Glover Island; uranium associated with Carboniferous rocks of the Deer Lake basin; and uranium associated with Topsails granitic intrusions.*

## INTRODUCTION

The Glover Group is an oceanic-derived sequence of rocks that has significant potential for mineralization (Cawood and Van Gool, 1998). It is the principal rock group underlying Glover Island, a large island at the southern end of Grand Lake, and the area of land just east of the island (Figures 1 and 2). Because of the mineral potential of the Glover Group, Glover Island has been a site of active mineral exploration for over 30 years. In 2002, Glover Island was designated as a public reserve and the area southeast of it as wildlife and provisional ecological reserves to protect the endangered Newfoundland Pine Marten. The reserve areas cover large parts of the Glover Group and mineral exploration is currently permitted in the public and wildlife reserves with a permit only, under guidelines to minimize the impact of exploration activities on the Pine Marten; exploration is not allowed in the provisional ecological reserve areas.

This study was initiated to delineate mineral potential within the Glover Group prior to permanent reserve designation, to provide baseline data on surficial geochemistry, and to assist mineral exploration efforts in the area. Till geochemistry was chosen for its effectiveness in delineating mineral potential in other areas (e.g., Snegamook Lake, Labrador, McCuaig and Taylor, 2005) and effect in stimulating staking activity after the release of data (e.g., Bonavista Peninsula, Newfoundland; Batterson and Taylor, 2001).

## LOCATION AND ACCESS

The study area encompasses the entire Glover Group, exposed on Glover Island and on the southeastern shore of Grand Lake. The study area covers parts of 1:50 000 scale NTS map areas 12A/12 and 12A/13 and is inaccessible by vehicle. The few logging roads present are deteriorating rapidly due to lack of use, especially those on Glover Island. Roads on the mainland part of the study area are cut off from other road networks by washouts, and streams are too shallow and rocky for boats. Grand Lake provides access via boat, but the steep shoreline and high cliffs limit further access; hence access to the area is mostly by helicopter.

## SETTING

Glover Island is a boggy plateau having steep cliffs on its northwestern and southern shores, and a few hilly areas in the hinterland. Its highest peak is 595 m asl, about 510 m above the surface of Grand Lake. The region southeast of Glover Island is part of the Long Range Mountains, and forms a glacially dissected plateau, with steep cliffs flanking its western shore on Grand Lake and its southern shore on Little Grand Lake. The Topsails Igneous Suite in the east forms high promontories that overlook the boggy plateau to the west (highest peak 719 m asl) and is part of The Topsails.

## BEDROCK GEOLOGY

When the Iapetus Ocean closed during the Middle Ordovician Taconic Orogeny, ophiolitic Dunnage Zone rocks were thrust northwestward over the Grenvillian basement of the Humber Zone (e.g., Williams, 1979). The Baie Verte–Brompton Line, the suture which separates the two zones, is represented in the study area by the Cabot Fault; it lies west of Glover Island beneath Grand Lake (Cawood *et al.*, 1996).

**Figure 1.** Location of study area.

## Humber Zone

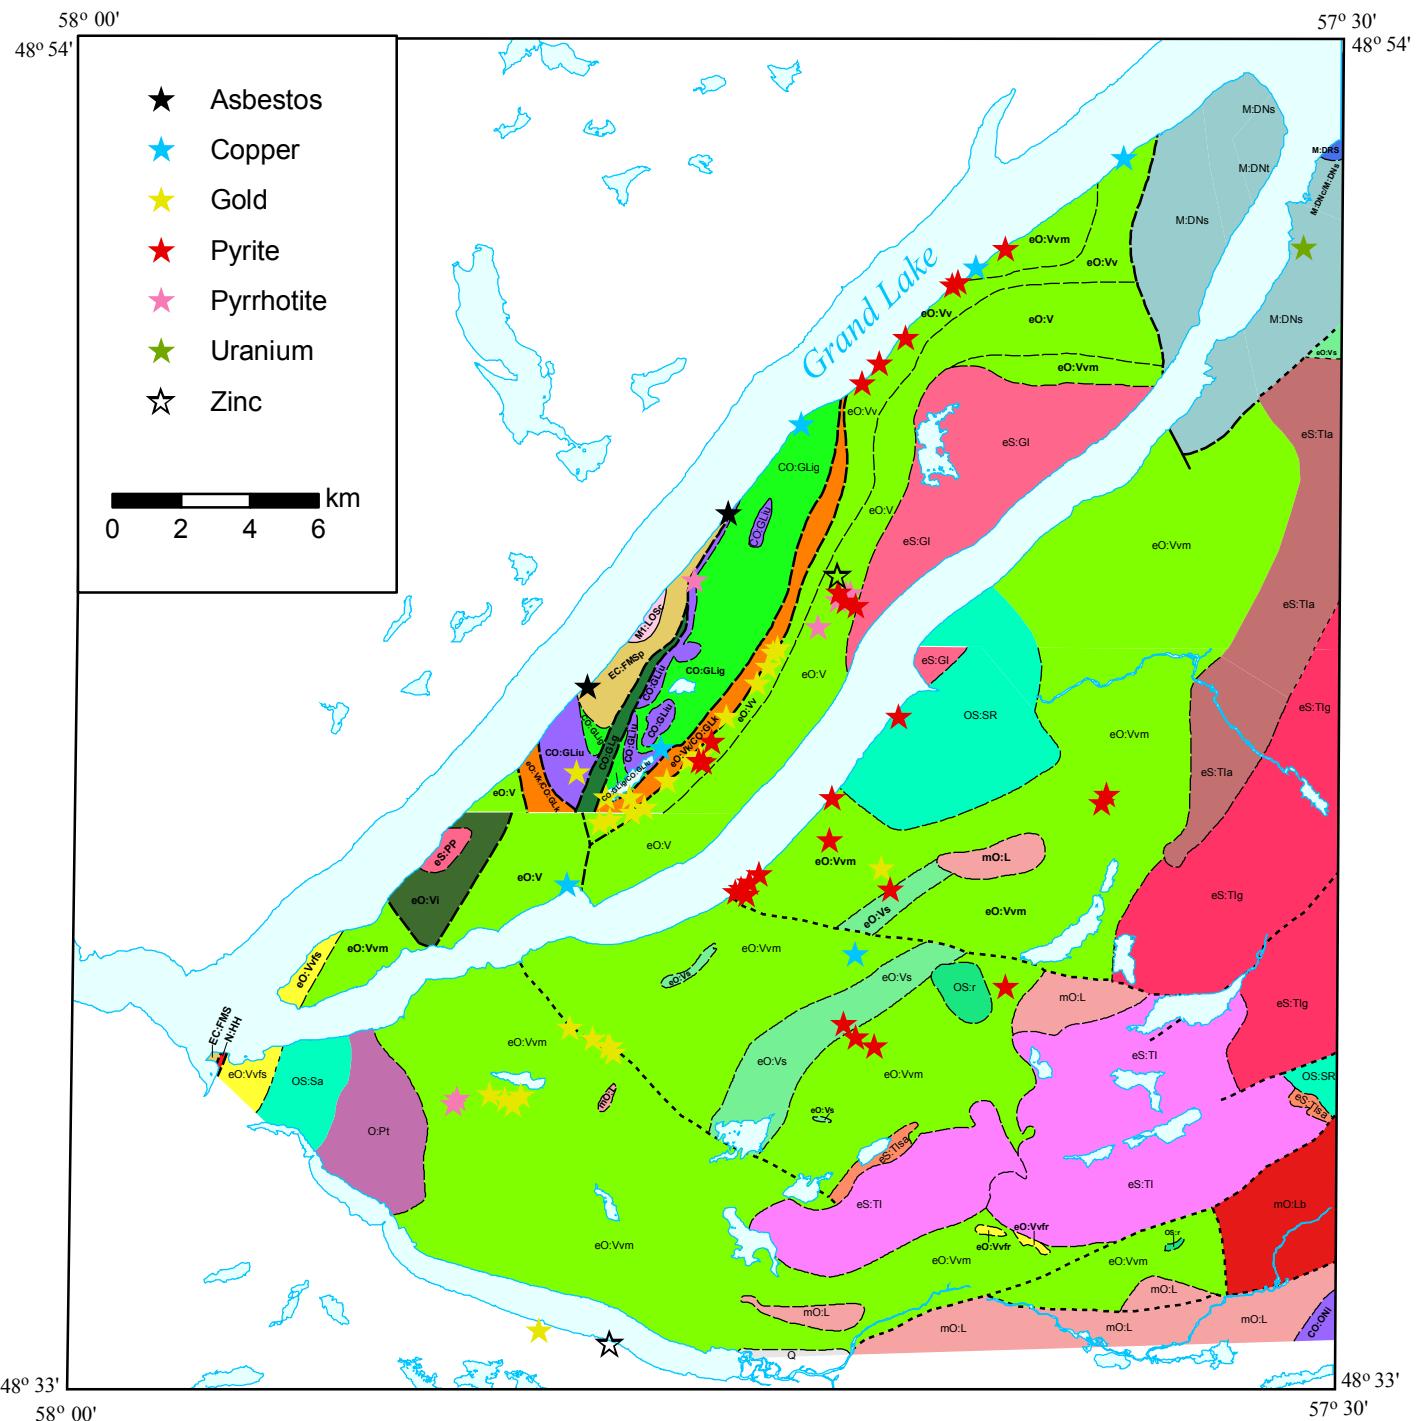

There are only a few rocks of Laurentian margin affinity in the study area and most are found west of Grand Lake. A small area on western Glover Island exposes the early Mesoproterozoic Corner Brook Lake Complex. It consists of granitoid banded gneisses (Cawood and Van Gool, 1998; Cawood *et al.*, 1996). The Corner Brook Lake Complex is unconformably overlain by the (age?) South Brook Formation which includes psammitic and pelitic schists, minor marble, amphibolite and conglomerate (Cawood and Van Gool, 1998; Cawood *et al.*, 1996). A small part of the Neoproterozoic Hare Hill Granite, a massive to foliated red granite, outcrops at the mouth of Lewaseechjeech Brook (Currie and van Berkel, 1992).

## Dunnage Zone

Many of the Dunnage Zone rocks are ophiolites and other mafic and ultramafic rocks that form part of the Iapetus Ocean basin. The Grand Lake Complex is dominated by gabbro and is considered to be a vestige of Iapetan oceanic crust obducted during the Taconic Orogeny. The complex is Late Cambrian to Early Ordovician and forms the hangingwall of the Grand Lake Complex Thrust Fault (Knapp, 1983). Other components of the complex include ophiolitic ultramafic rocks, sheeted diabase dykes, green-schist-facies, semi-pelitic schists, talc–carbonate schist, minor trondhjemite and diorite, and crosscutting mafic dykes (Cawood and Van Gool, 1998; Cawood *et al.*, 1996; Currie and van Berkel, 1992; Knapp, 1983; Szybinski *et al.*, 1995). The Kettle Pond Shear Zone separates the Grand Lake Complex from the Glover Group to the east (Cawood and Van Gool, 1998b). The Glover Group is Early Ordovician (Currie, 1987), is variably deformed, and is metamorphosed to greenschist facies (Knapp, 1983). The group is composed of steeply dipping ophiolites and mafic to felsic plutonic, volcanic and volcaniclastic rocks (Cawood and Van Gool, 1998; Cawood *et al.*, 1996). Lower sequences include conglomerate, shale and chert (Cawood and Van Gool, 1998; Cawood *et al.*, 1996; Knapp, 1983; Szybinski *et al.*, 1995; Whalen, 1993).

A number of younger plutons have intruded the ophiolitic and younger clastic rocks. The Pierre's Pond Plutonic Suite, at the northern end of Little Grand Lake, consists of Early to Middle Ordovician foliated hornblende–biotite tonalite (Whalen, 1993). Farther east, foliated Middle Ordovician granodiorite and tonalite intrusions make up the Lewaseechjeech Brook Plutonic Suite (Whalen, 1993). The Bottom Brook Intrusions are small and consist of gabbroic and ultramafic rocks (Currie and van Berkel, 1992; Williams, 1985). The Rainy Lake Complex has intruded the Glover Group, just east of Glover Island. This complex is composed of gabbro, granodiorite, granite and tonalite (Whalen, 1993). The Glover Island Granodiorite has also intruded the Glover Group. It is made up of beige to grey foliated granodiorite of Late Ordovician age (Cawood and Van Gool, 1998; Cawood *et al.*, 1996; Whalen, 1993). The Early Silurian Little Paddle Point Pluton, found near the southwestern tip of Glover Island includes brecciated granodiorite, granite and some pegmatite. It may be related to the Glover Island Granodiorite (Cawood and Van Gool, 1998). The Early Silurian Topsails Igneous Suite forms the higher hills in the east of the study area. It is composed of a variety of undeformed granitoids and also intrudes the Glover Group. The suite has been cut by mafic dykes (van Berkel and Currie, 1988; Whalen, 1993).

The Mississippian Deer Lake Group, at the north end of Glover Island, contains red to grey conglomerate and sandstone, lacustrine mudstone and limestone. These rocks have been assigned to the North Brook Formation (Cawood and Van Gool, 1998; Cawood *et al.*, 1996; Knight, 1994). The overlying

Rocky Brook Formation consists of mudstone, oil shale and limestone, and outcrops at the northeastern tip of the area surveyed (Cawood and Van Gool, 1998; Knight, 1994).

## ECONOMIC GEOLOGY

Oceanic rocks of the Dunnage Zone are known to contain gold and base metals – this area is no exception. Gold occurs along the Humber–Dunnage boundary, (within the Kettle Pond Shear Zone) on Glover Island (Cawood and Van Gool, 1998) and also along a shear zone between Grand Lake and Little Grand Lake (Currie and van Berkel, 1992). Mafic and ultramafic intrusions on Glover Island and areas east contain gold, platinum and palladium (van Berkel and Currie, 1988), while the Glover Group hosts copper mineralization (Cawood and Van Gool, 1998).

The Deer Lake Group hosts uranium mineralization, including the Grand Pond Point #2 showing within the study area.

## QUATERNARY GEOLOGY

## SURFICIAL GEOLOGY

The surficial geology of the study area mapped by Batterson (1995, 2000, 2003) is variable. Generally, thick bouldery till is found in low-lying and flat areas, thinner till on slopes, and a patchy till veneer on hilltops. The southeast part of the study area is mostly covered by till veneers and exposed bedrock; and along the margins of Grand Lake and Little Grand Lake, steep slopes result in extensive areas of colluvium. Many of the low-relief areas have bog and organic deposits cover.

## ICE FLOW

Batterson (2003) described the regional ice-flow patterns found within the Humber Basin. The study area is dominated by ice flow from an ice centre in The Topsails and using evidence from striations, landforms and clast dispersal, he documented a consistent westward to west-northwestward flow. This forms a radial pattern with

direction of flow changing from westward flow in the south to west-northwestward in the north. There is some evidence for late southward flow around the west end of Little Grand Lake but this apparently affected only a small area. Few striations were identified during 2005 field-work but those that were observed generally support the ice-flow pattern described.

## METHODS

### SAMPLING

The study area was sampled mainly by helicopter, but a few of the older woods roads were accessed by mountain bike or on foot after helicopter drop-off. In total, 206 till samples weighing about 1 kg each were taken; these were placed in Kraft paper bags and air dried. The sample density in the area east of Glover Island was 1 sample per 3.3 km<sup>2</sup>, but the sample density for the road and surrounding area is denser, at 1 sample per 1.5 km<sup>2</sup>. Glover Island is sampled at a spacing of 1 per 3.6 km<sup>2</sup>, except for the central road and surrounding area, which is 1 sample per 1.6 km<sup>2</sup> (Figure 3).

A few samples were acquired from old road-cuts (average depth 330 cm), but most were taken from test-pits using a shovel and pick (average depth 50 cm); most samples were taken from the C-horizon (66%). In areas where the B-horizon was extensive or where the till was too thin for a C-horizon to be present, B- or BC- horizon samples were taken (13% and 21% respectively).

### GEOCHEMICAL ANALYSIS

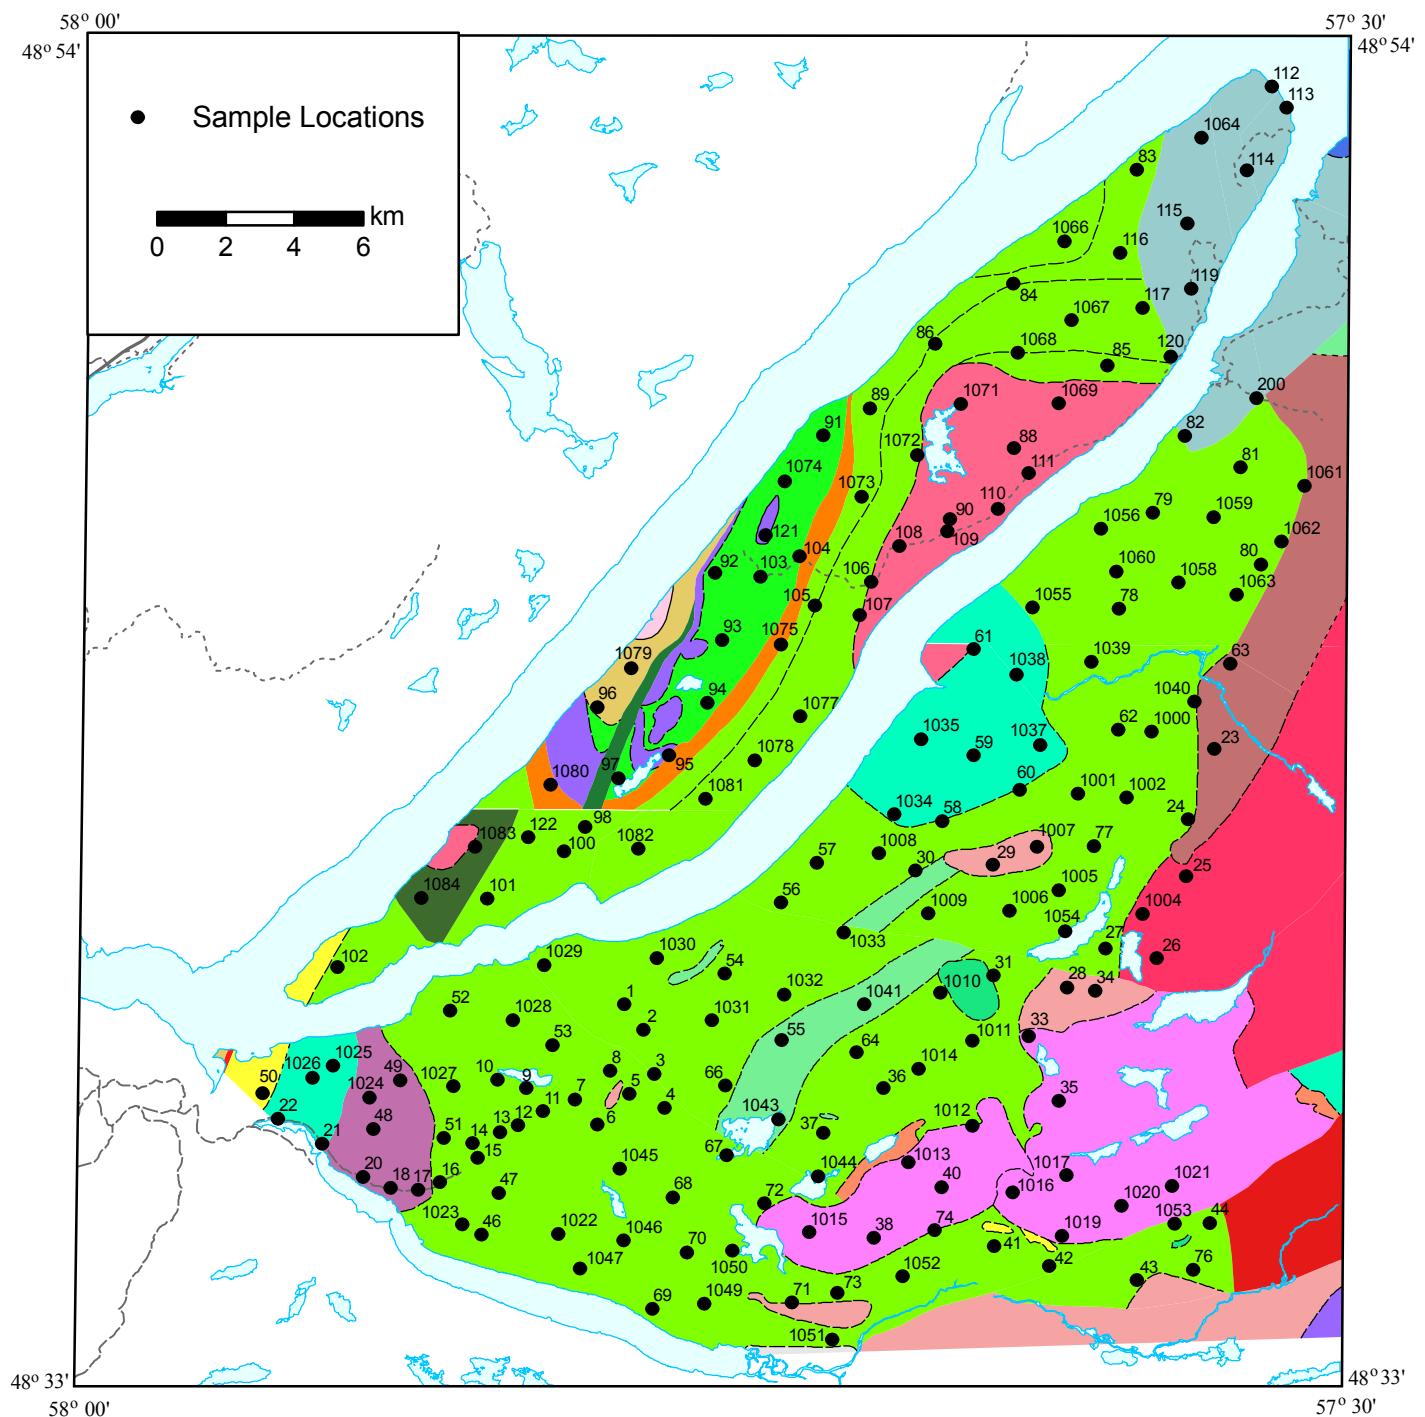

The silt-clay fraction of the till samples was analyzed for trace elements at the Geological Survey laboratory. The samples were oven-dried at 40°C and were sieved through 63 µm stainless steel sieves. The <63 µm fraction was analyzed.

### ANALYTICAL METHODS

A suite of 206 samples was analyzed for trace-element geochemistry. At the Geological Survey laboratory, Al, As, Ba, Be, Ca, Cd, Ce, Co, Cr, Cu, Dy, Fe, K, La, Li, Mg, Mn, Mo, Na, Nb, Ni, P, Pb, Rb, Sc, Sr, Ti, V, Y, Zn and Zr were analyzed with inductively coupled plasma–emission spectroscopy (ICP-ES). Activation Laboratories (Ancaster, Ontario) did instrumental neutron activation analysis (INAA) for the following elements: Ag, As, Au, Ba, Br, Ca, Ce, Co, Cr, Cs, Eu, Fe, Hf, Hg, Ir, La, Lu, Mo, Na, Nd, Ni, Rb, Sb, Sc, Se, Sm, Sn, Sr, Ta, Tb, Th, U, W, Yb, Zn, Zr. Field duplicates and control reference materials are included incognito in all internal and external analyses. The trace elements are labelled with their elemental abbreviation, a numeric code to distinguish the analysis type and the applicable unit of measurement (Table 1).

#### Gravimetric Analysis (LOI)

Organic carbon content was estimated from weight loss-on-ignition (LOI) during a controlled combustion, in which 1 g aliquots of sample were gradually heated to 500°C in air, over a 3-hour period.

**Figure 3.** Sample numbers and locations.

### Inductively Coupled Plasma–Emission Spectroscopy (ICP-ES)

For these analyses, the residue of the 1g aliquot of sample remaining from the LOI determination was digested in a mixture of 15 ml of concentrated hydrofluoric acid, 5 ml of concentrated hydrochloric acid, and 5 ml of 50 volume percent  $\text{HClO}_4$  in a 100 ml teflon beaker, and was allowed to stand overnight before being heated to dryness on a hot plate. The residue was taken up in 10 volume percent hydrochlo-

ric acid by gentle heating on a hot plate, was allowed to cool and was made up to 50 ml with 10 percent volume hydrochloric acid (Wagenbauer *et al.*, 1983). For most elements dissolution is total with the exception of Cr from chromite, Ba from barite and Zr from zircon.

### **Instrumental Neutron Activation Analysis (INAA)**

An approximately 30 g aliquot is encapsulated and weighed in a polyethylene vial and irradiated with flux wires and an internal standard (1 for 11 samples) at a thermal neutron flux of  $7 \times 10^{11}$  n/cm<sup>2</sup>s. After seven days (to allow Na<sup>24</sup> to decay), the samples are counted on a high purity Ge detector with a resolution of better than 1.7 KeV. Using the flux wires, the decay-corrected activities are compared to a calibration developed from multiple certified international reference materials. The standard present is only a check on accuracy of the analysis and is not used for calibration purposes, 10 to 30 percent of the samples are checked by re-measurement.

### **QUALITY CONTROL**

Duplicate samples were taken at the same site in the field, as well as laboratory duplicates (duplicate analyses of random samples). The extent of correlation between duplicate analyses of the same sample, give a measure of analytical precision, and can be used to estimate data quality (Table 2). If the duplicate samples provide identical re-

#### **Note:**

If all samples are below detection limit, no value is reported. Sixteen field duplicate pairs and eleven laboratory duplicate pairs were used.

sults the correlation coefficient between the variables will be equal to 1. For elements that were analyzed using more than one method, the results were compared and the best method was chosen for mapping purposes. Duplicate data is not included in this report, but is available from the authors upon request.

For some elements, the analysis of duplicates yields poor results, as the samples chosen had levels that are close to the detection limit for that element. Thus, the method of correlating duplicate pairs yields little useful information. For this reason, it is difficult to evaluate the data quality for Au1, Ag1, Ca1, Cs1, Mo1, Ni1, Se1, Sn1, Sr1, Ta1, Tb1 and W1. Gold analyses are susceptible to the “nugget” effect, where the presence or absence of a native gold grain can cause differing results in duplicate samples.

For elements analyzed by both ICP and INAA, analysis of laboratory duplicates suggests that INAA is the better method for As and Fe; and ICP for Ba, Ca, Ce, Co, Cr, La, Mo, Na, Ni, Sc, Sr, Zn and Zr.

Examination of field duplicates indicates that the reproducibility of analyses is in most cases similar to analysis of laboratory duplicates, indicating that field sampling introduces little extra “noise” to the analysis, and that single samples can be considered representative of surface sediment geochemistry in the area for most elements. For the analytical method of choice, correlation coefficients between field duplicates are generally 0.6 or higher. Variation between duplicate field samples is higher than generally expected for K2, Fe2, Na2, and Ti2 but still show moderate positive correlations. Gold analyses appear more reproducible from the field duplicates rather than laboratory duplicates. This may be because the samples chosen for laboratory duplicates had values mostly close to detection limit, but suggest caution should be exercised in interpreting a single anomalous gold value.

## DATA PRESENTATION

Dot plots of selected elements (As, Au, Cu, Ni, Sb, U) are shown on page sized colour bedrock map bases. The dots represent values within a particular size range, chosen by picking natural breaks using the Jenks statistical method (Jenks, 1967). Dot plots of the remaining elements are available in Appendix 2. One hundred and ninety samples are mapped (excluding laboratory and field duplicates).

The appended data listings (Appendix 1) provide the analytical data for all of the elements analyzed. The accompanying CD-ROM provides the same data as Excel 2004 files and as comma delimited text files (.csv). The numeric code distinguishes the type of analysis and the laboratory at which the analysis was done (Table 1).

The summary statistics for the data set are given in Table 3.

## GEOCHEMICAL RESULTS AND INTERPRETATIONS

### INTER-ELEMENT CORRELATIONS

A correlation matrix was calculated to examine relationships between elements (Table 4). Gold shows a strong positive correlation with arsenic (0.69), and a moderate positive correlation with antimony (0.31) suggesting that arsenic and antimony might be used as “pathfinder” elements for gold in the area, given the difficulty of interpreting gold analyses due to the nugget effect. Copper shows correlations with cobalt

(0.59), and magnesium (0.62). Uranium is correlated with beryllium (0.60), potassium (0.52), niobium (0.60), rubidium (0.56), zirconium (0.59), hafnium (0.67), lutetium (0.64), and thorium (0.72). Nickel shows correlations with cobalt (0.56), chromium (0.78), lithium (0.54), magnesium (0.73), and zinc (0.59). This geochemical pattern likely is associated with ultramafic rocks.

## **Gold**

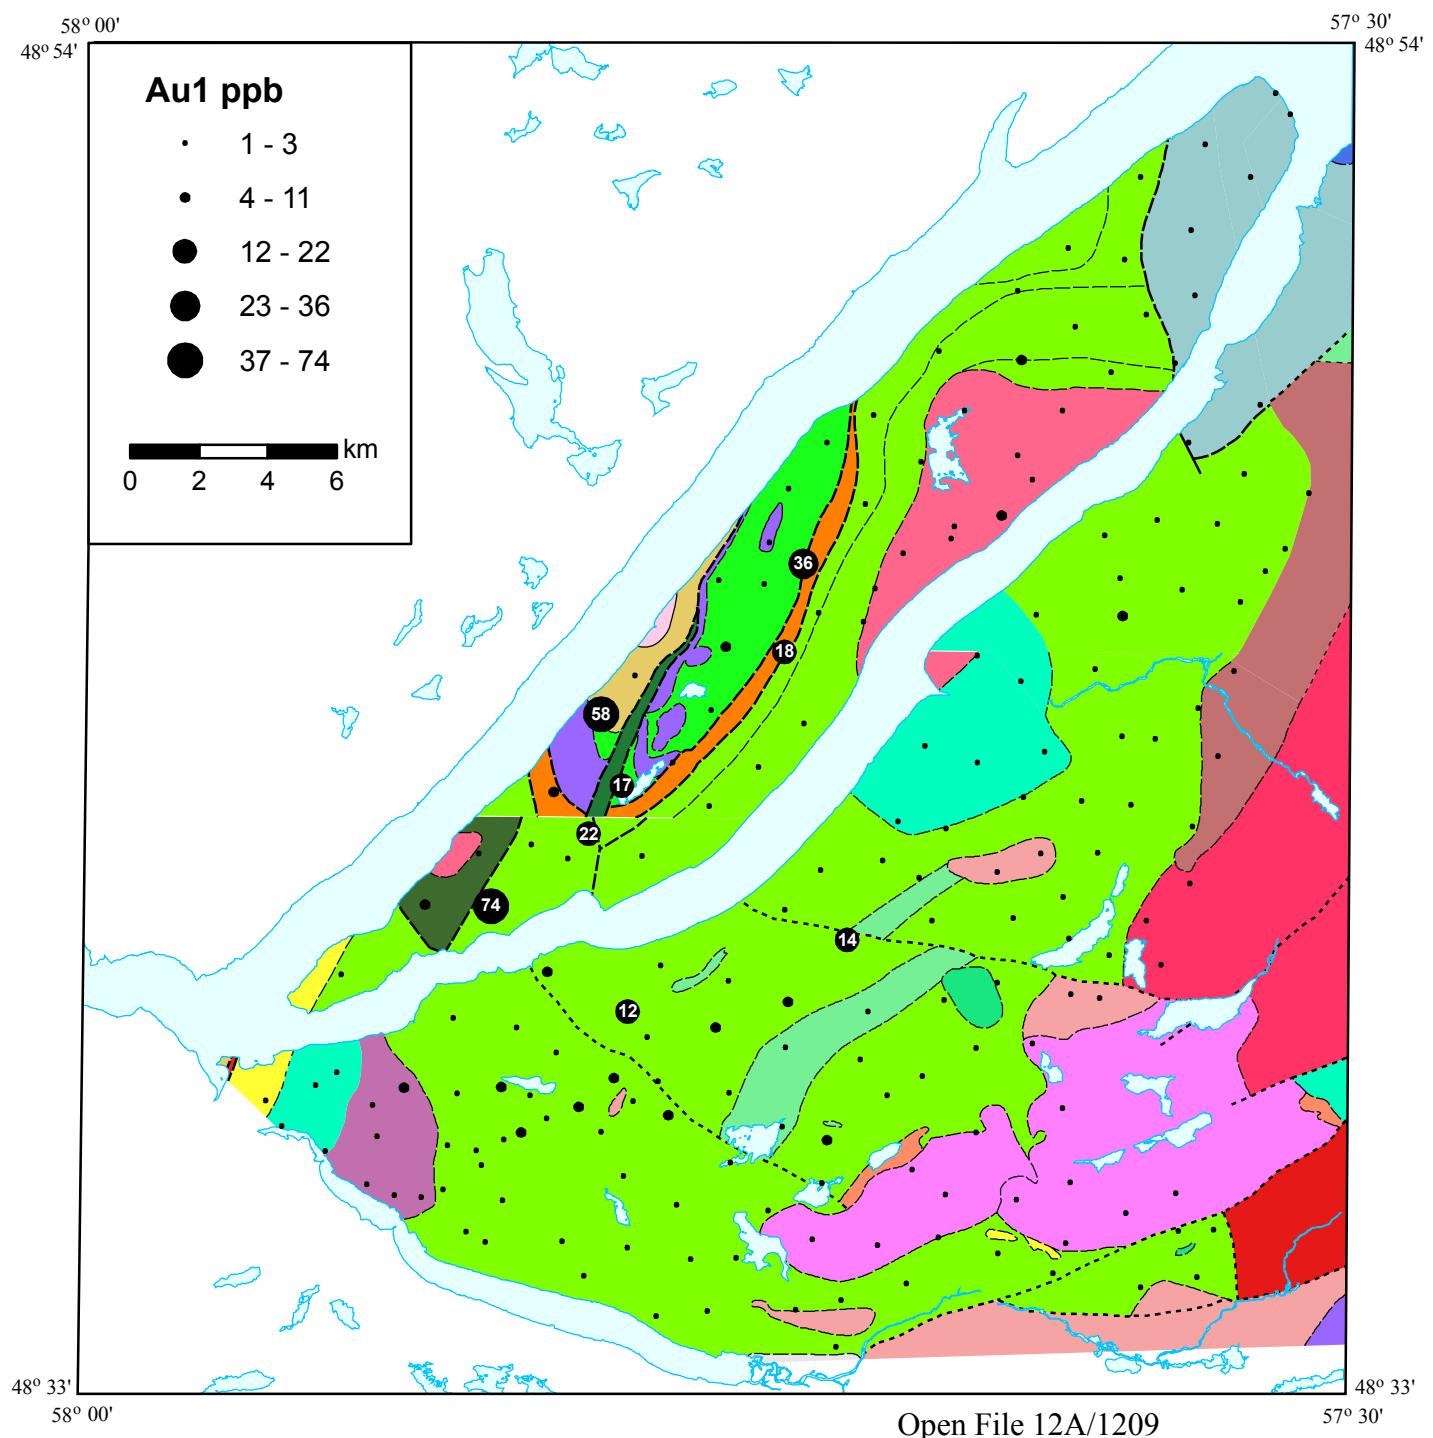

Interpretation of gold results is distorted by the “nugget” effect in areas where particulate gold is common. Geochemical results can be unduly influenced by the presence or absence of single gold grains. Thus interpretation is more reliable when based on groups of gold values. The highest six results for gold are all located on Glover Island, where several gold occurrences are known (Figure 4). The highest value (74 ppb) is located 5 km southwest of the Kettle Pond gold showings and is unlikely to be related to glacial dispersal from known showings. The difficulty of reproducing gold analyses is illustrated however by the results of a laboratory duplicate analysis on this sample which yielded the lower but still significant result of 8 ppb. The second highest result (58 ppb) is located 2 km northwest of Kettle Brook, and may be related to glacial dispersal, or to unknown occurrences. One sample yielding a result of 36 ppb is located 2 km north of a cluster of gold showings and may be unrelated to these. Two samples from the area south of Glover Island gave results of 12 and 14 ppb. The 12 ppb sample is not located close to any known showings. The 14 ppb sample is located less than 2 km from the Patino copper indication, and 2 km southwest of the Ridge Creek gold indication.

## **Arsenic**

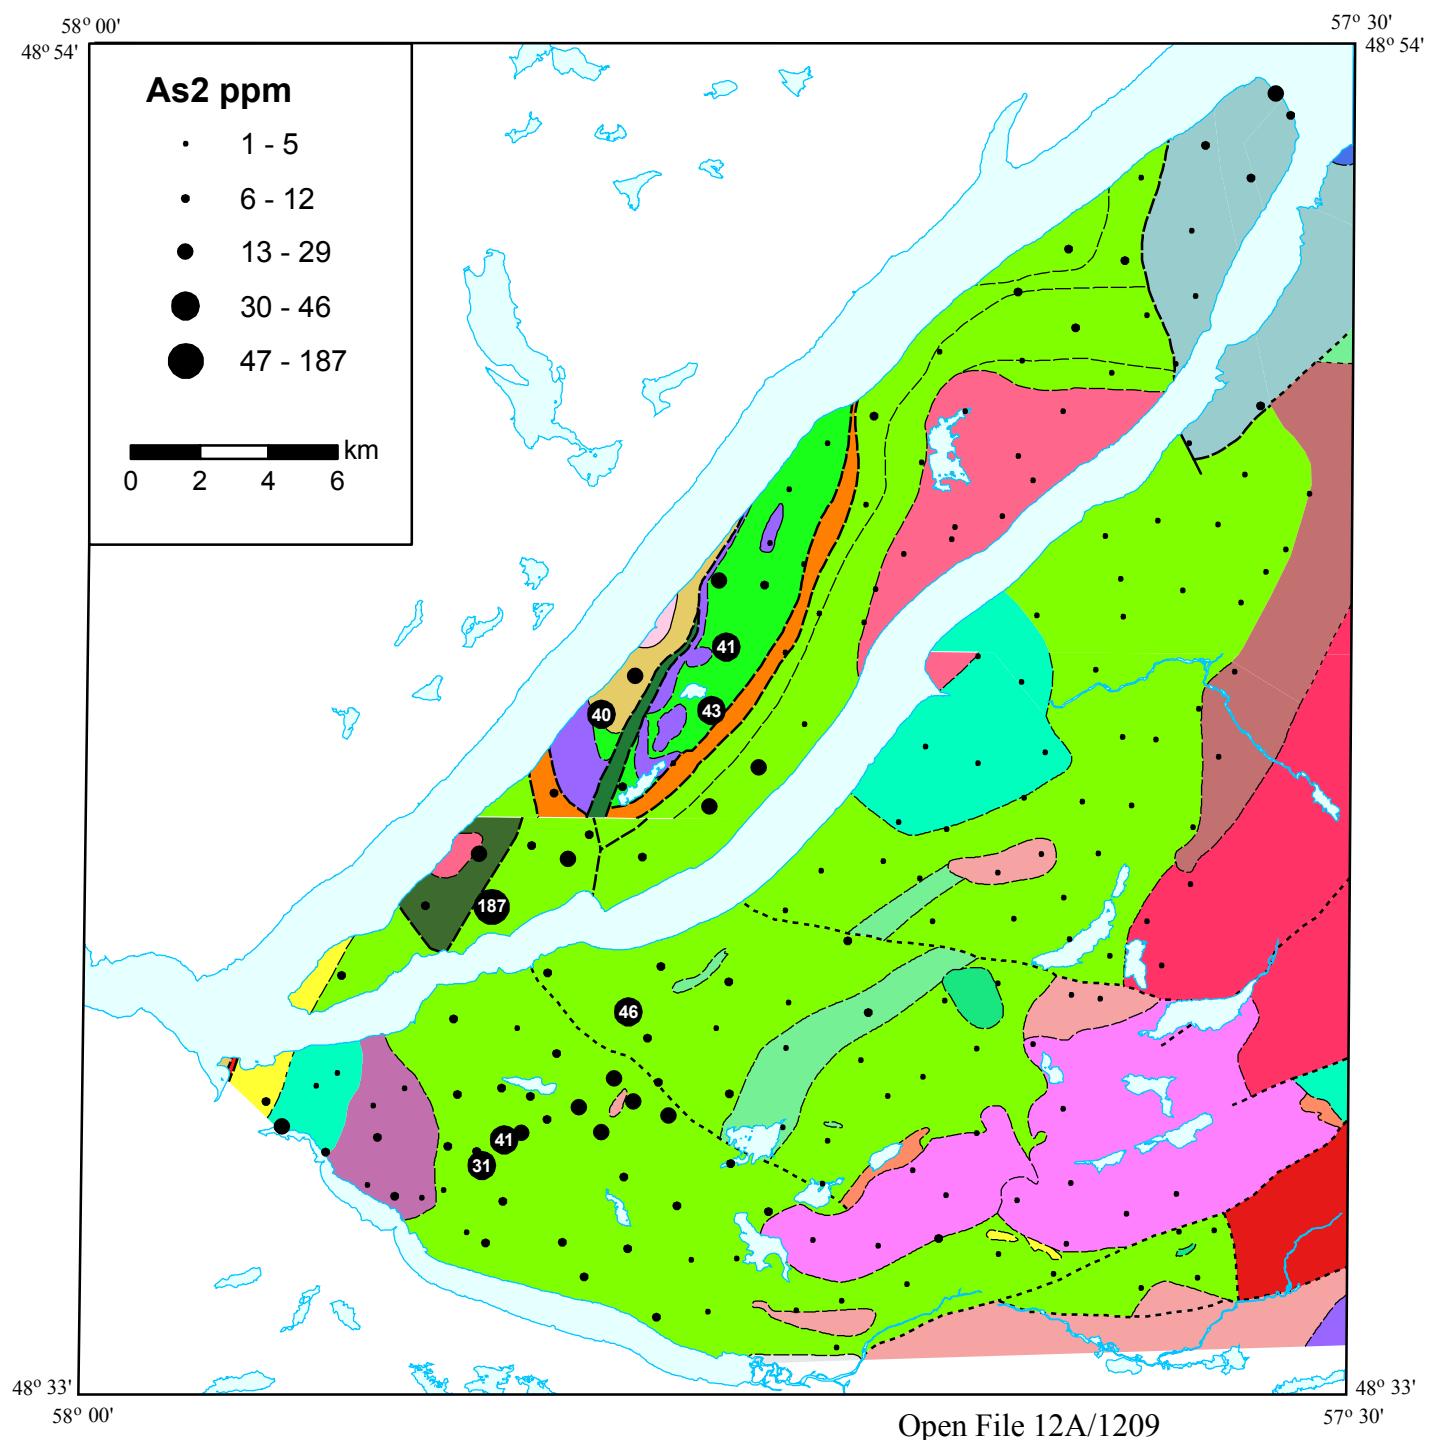

Sometimes, it is difficult to reproduce gold analyses, and arsenic is commonly used as a pathfinder element because of its association with gold in mineralization. In the Glover Group, this relationship seems to exist, as shown by high arsenic values being associated with the high gold values mentioned above, and high inter-element correlation (Figure 5). Thus, high arsenic values without associated gold values may indicate gold mineralization. A group of high arsenic values is found south of the Martin Prospect between Little Grand Lake and Grand Lake. High arsenic values often, but not always, associated with gold are found on Glover Island. Twenty-two samples gave arsenic values in excess of the Canadian Council of Ministers of the Environment residential guidelines for arsenic in soil (12 ppm), but as this area has no permanent dwellings, this is not of great concern.

## **Copper**

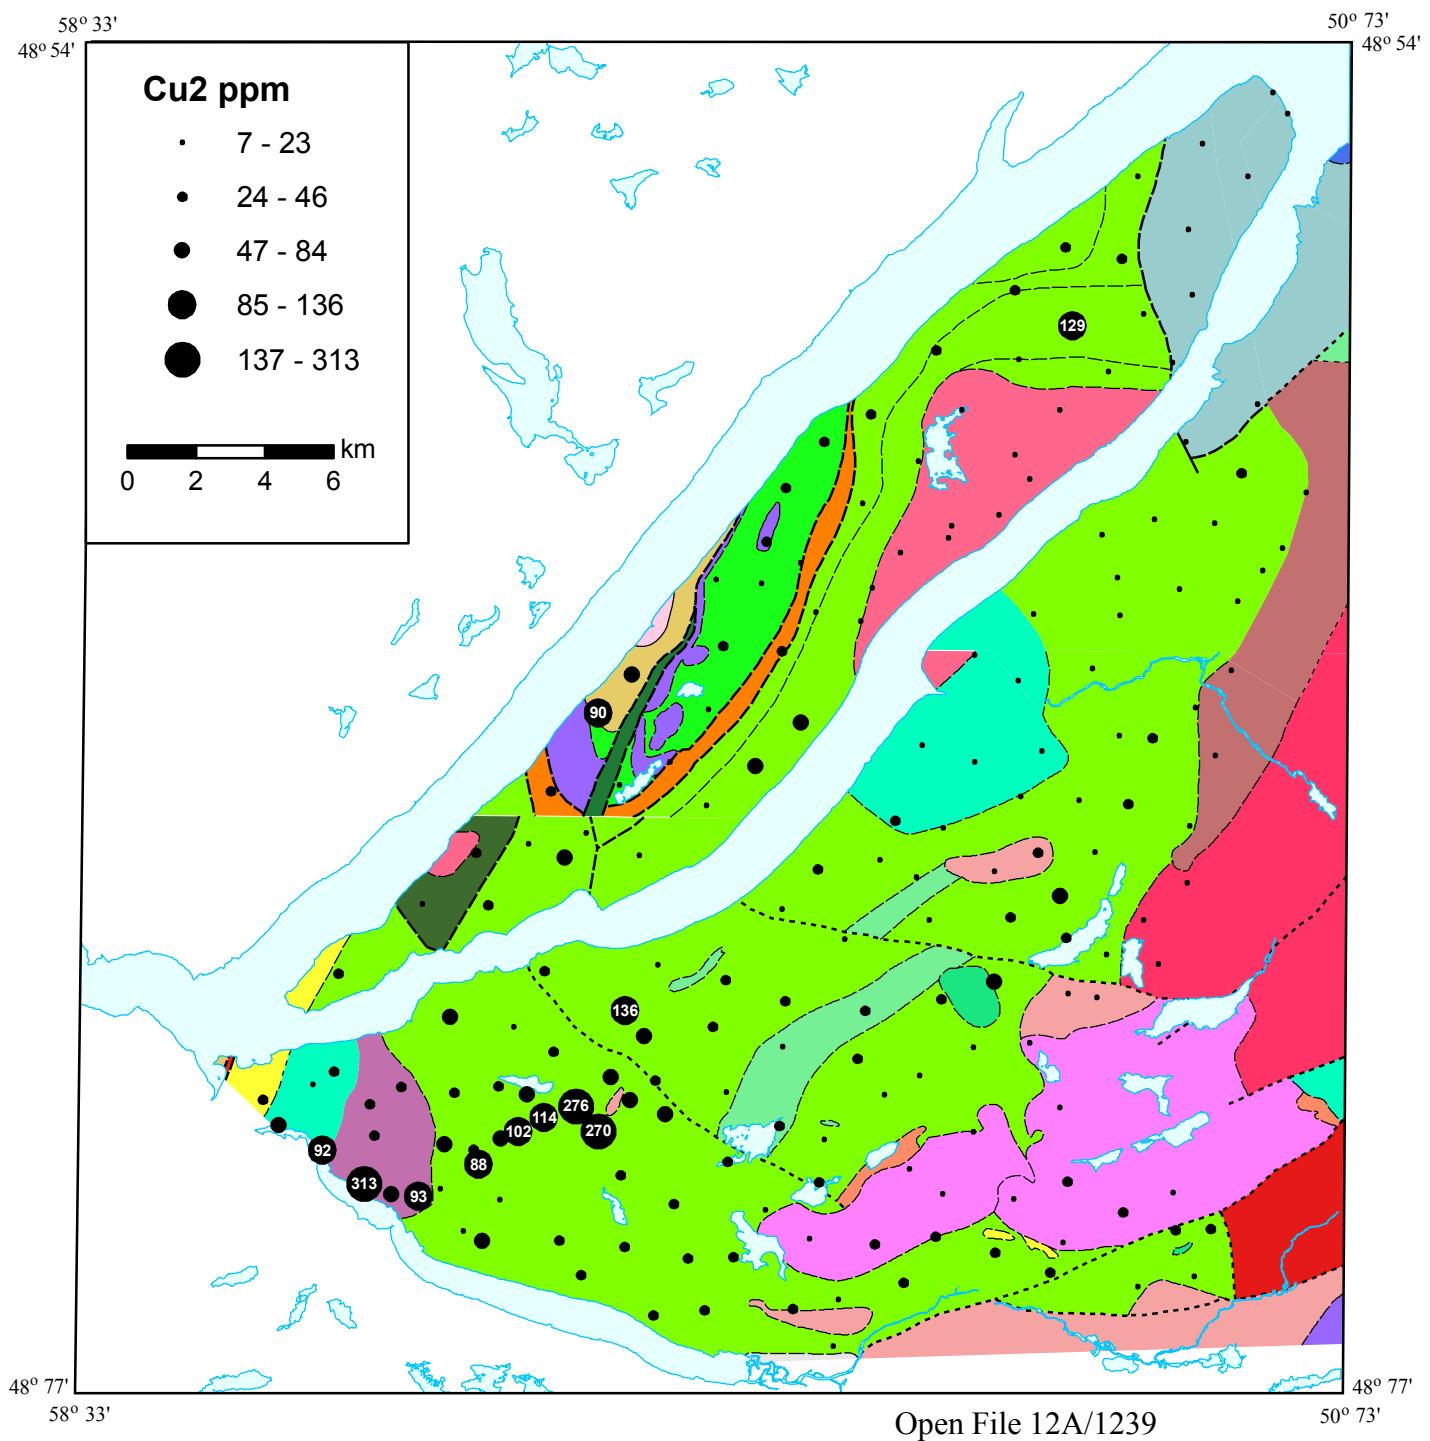

Anomalous copper values are concentrated in the southwest of the study area, extending eastward from the outlet of Little Grand Lake to Youngs Pond (Figure 6). Nine samples in this area yielded values ranging from 88 to 313 ppm. All these samples were collected adjacent to a disused logging road, whilst foot-traversing on the first two days of field work. There was concern that there might be some analytical problems because these were the first samples analyzed and so a subset was re-analyzed, but yielded comparable results. The Youngs Pond showings of pyrrhotite lie 2 km to the north of these sample sites and indications of gold are known along or near the logging road. Thus, these copper values likely reflect mineralization in bedrock in the area. The highest value (313 ppm) is found on the shores of Little Grand Lake, and in an area mapped as being underlain by Devonian granite; high copper in bedrock in this area would be surprising so perhaps this result reflects glacial dispersal from a source to the east.

**Figure 4.** Distribution of gold in till.

**Figure 5.** Distribution of arsenic in till.

**Figure 6.** Distribution of copper in till.

## **Nickel**

Five of the highest nickel values form a group in the Kettle Pond area, with nickel content ranging from 68 to 222 ppm (Figure 7). Zinc values are also comparatively high in this area (up to 129 ppm). Descriptions of the mineral occurrences in this area do not mention sulphide mineralization apart from pyrite and it is possible that the nickel found in tills in this area does not relate to the known gold mineralization. Four other anomalous values (86-134 ppm) are found from samples taken on the northern part of Glover Island, where there are no known mineral occurrences. Two of the four samples were taken from areas mapped as underlain by Carboniferous rocks. Samples in this area also show anomalous zinc values, ranging from 81 to 122 ppm.

## **Antimony**

Antimony is also used as a pathfinder for gold. Anomalous antimony values are found from two areas, close to the Kettle Pond occurrences, and south of Youngs Pond (Figure 8). Although the Youngs Pond area does not show any anomalous results for gold, the combination of arsenic, antimony and copper anomalies suggest this is an area of potential for gold mineralization.

## **Uranium**

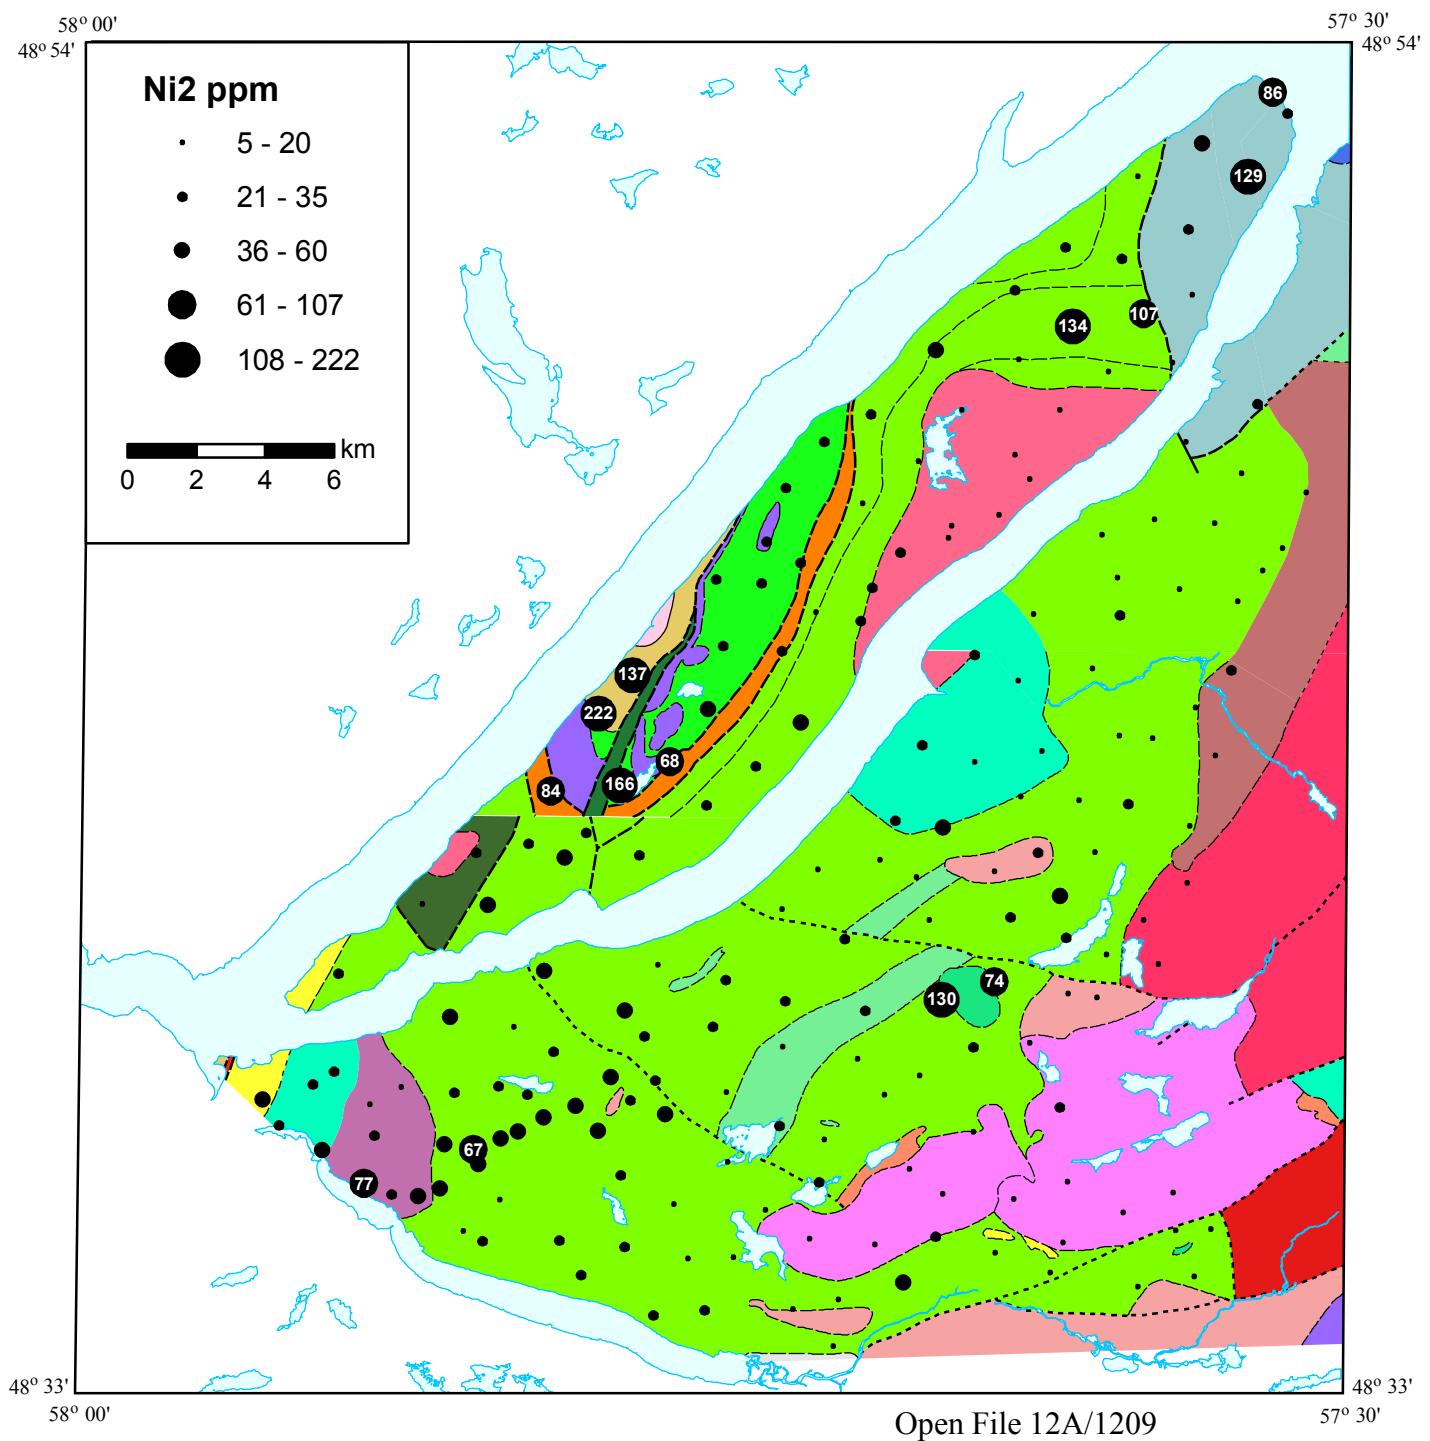

Uranium shows a distinct pattern (Figure 9) and clusters of relatively high uranium values are found over the Carboniferous rocks in the north end of Glover Island, and extending south to the northern part of the Glover Group. Uranium mineralization is known from these rocks, with the Grand Pond Point #2 indication being found along the shores of Grand Lake in this area. The highest uranium value (4.3 ppm) is found close to the contact between the Topsails granite and Glover Group rocks east of Little Grand Lake. It is associated with five other anomalous results ranging from 3-3.5 ppm, as well as relatively high results for cerium, niobium and yttrium. Although these uranium anomalies are relatively low, they are comparable to values from till in areas of known mineralization in the Central Mineral Belt of Labrador (McCuaig and Taylor, 2005).

## **CONCLUSIONS**

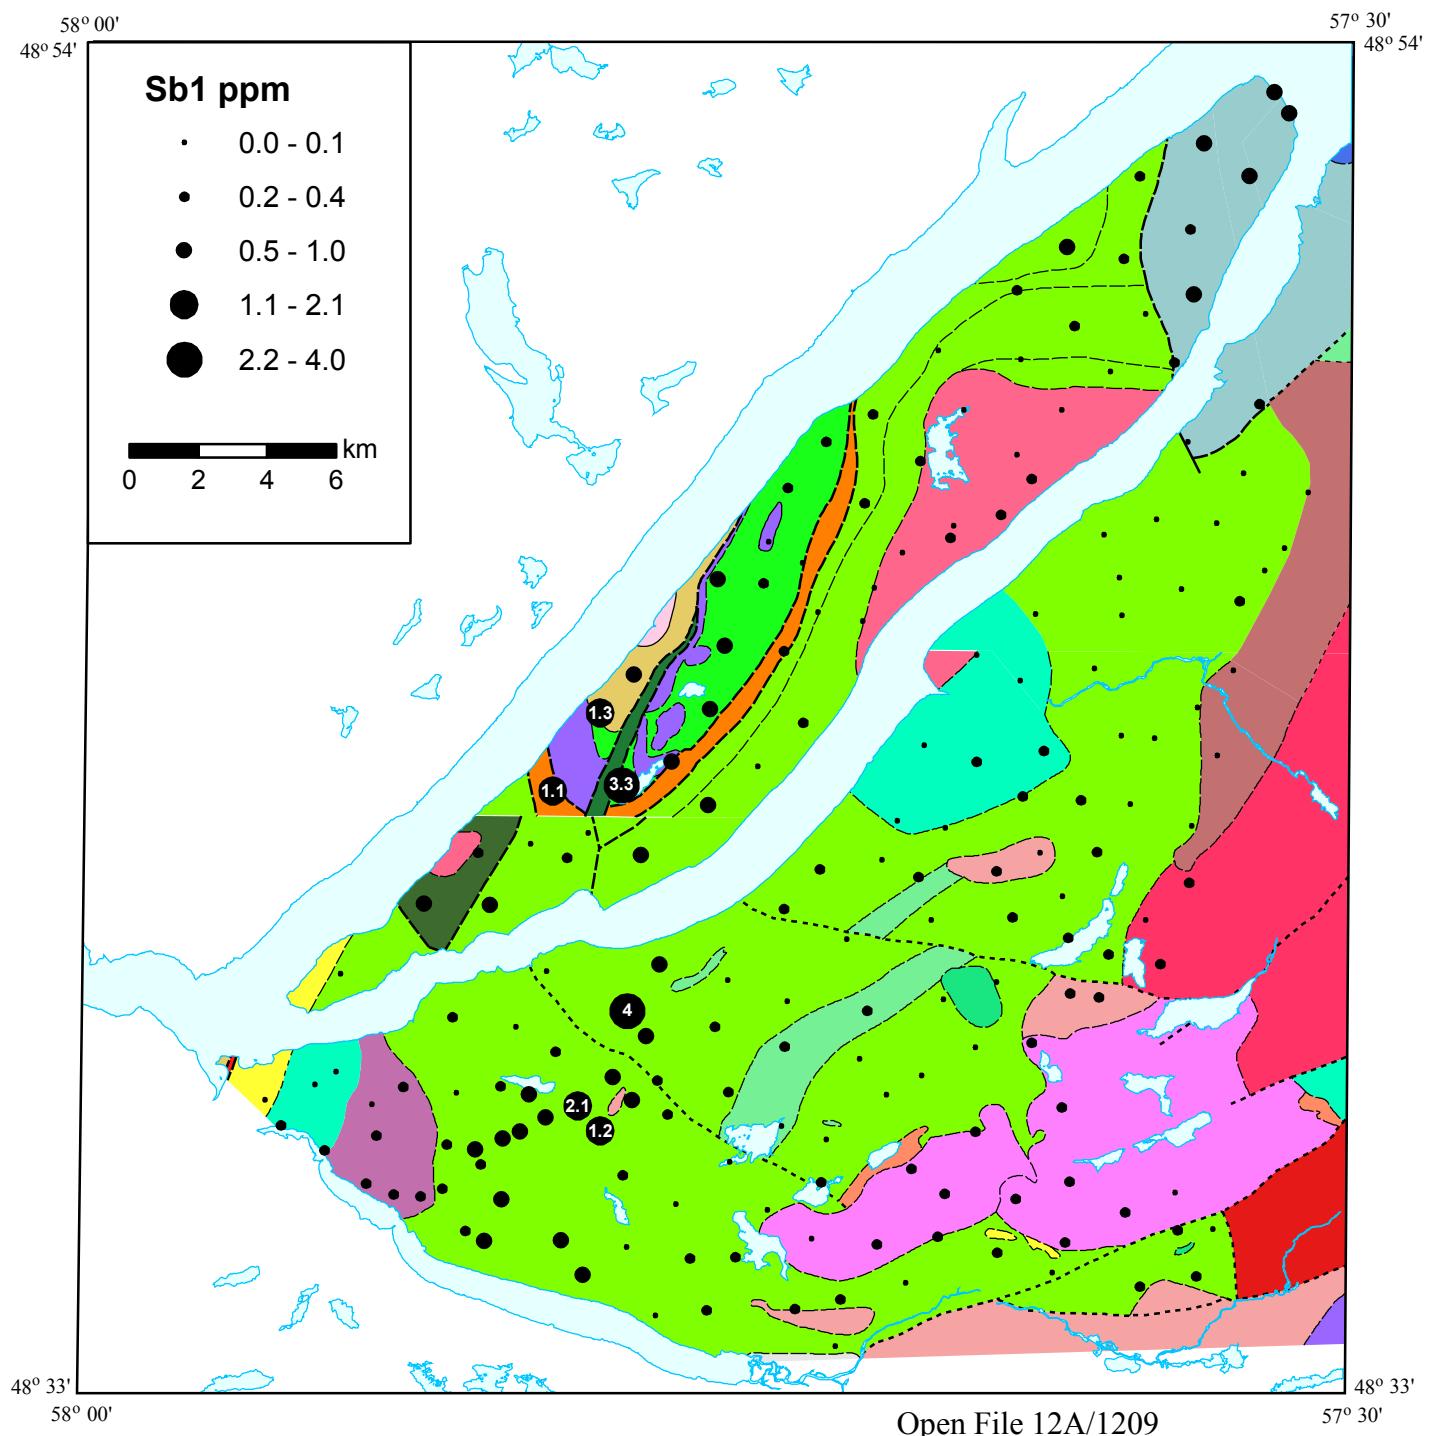

Till geochemistry has identified several possible targets for exploration, including gold mineralization on Glover Island in areas with no known gold showings, possible gold mineralization associated with arsenic between Little Grand Lake and Grand Lake, nickel on Glover Island, uranium associated with Carboniferous rocks of the Deer Lake basin, and uranium associated with the Topsails granitic intrusions.

## **ACKNOWLEDGMENTS**

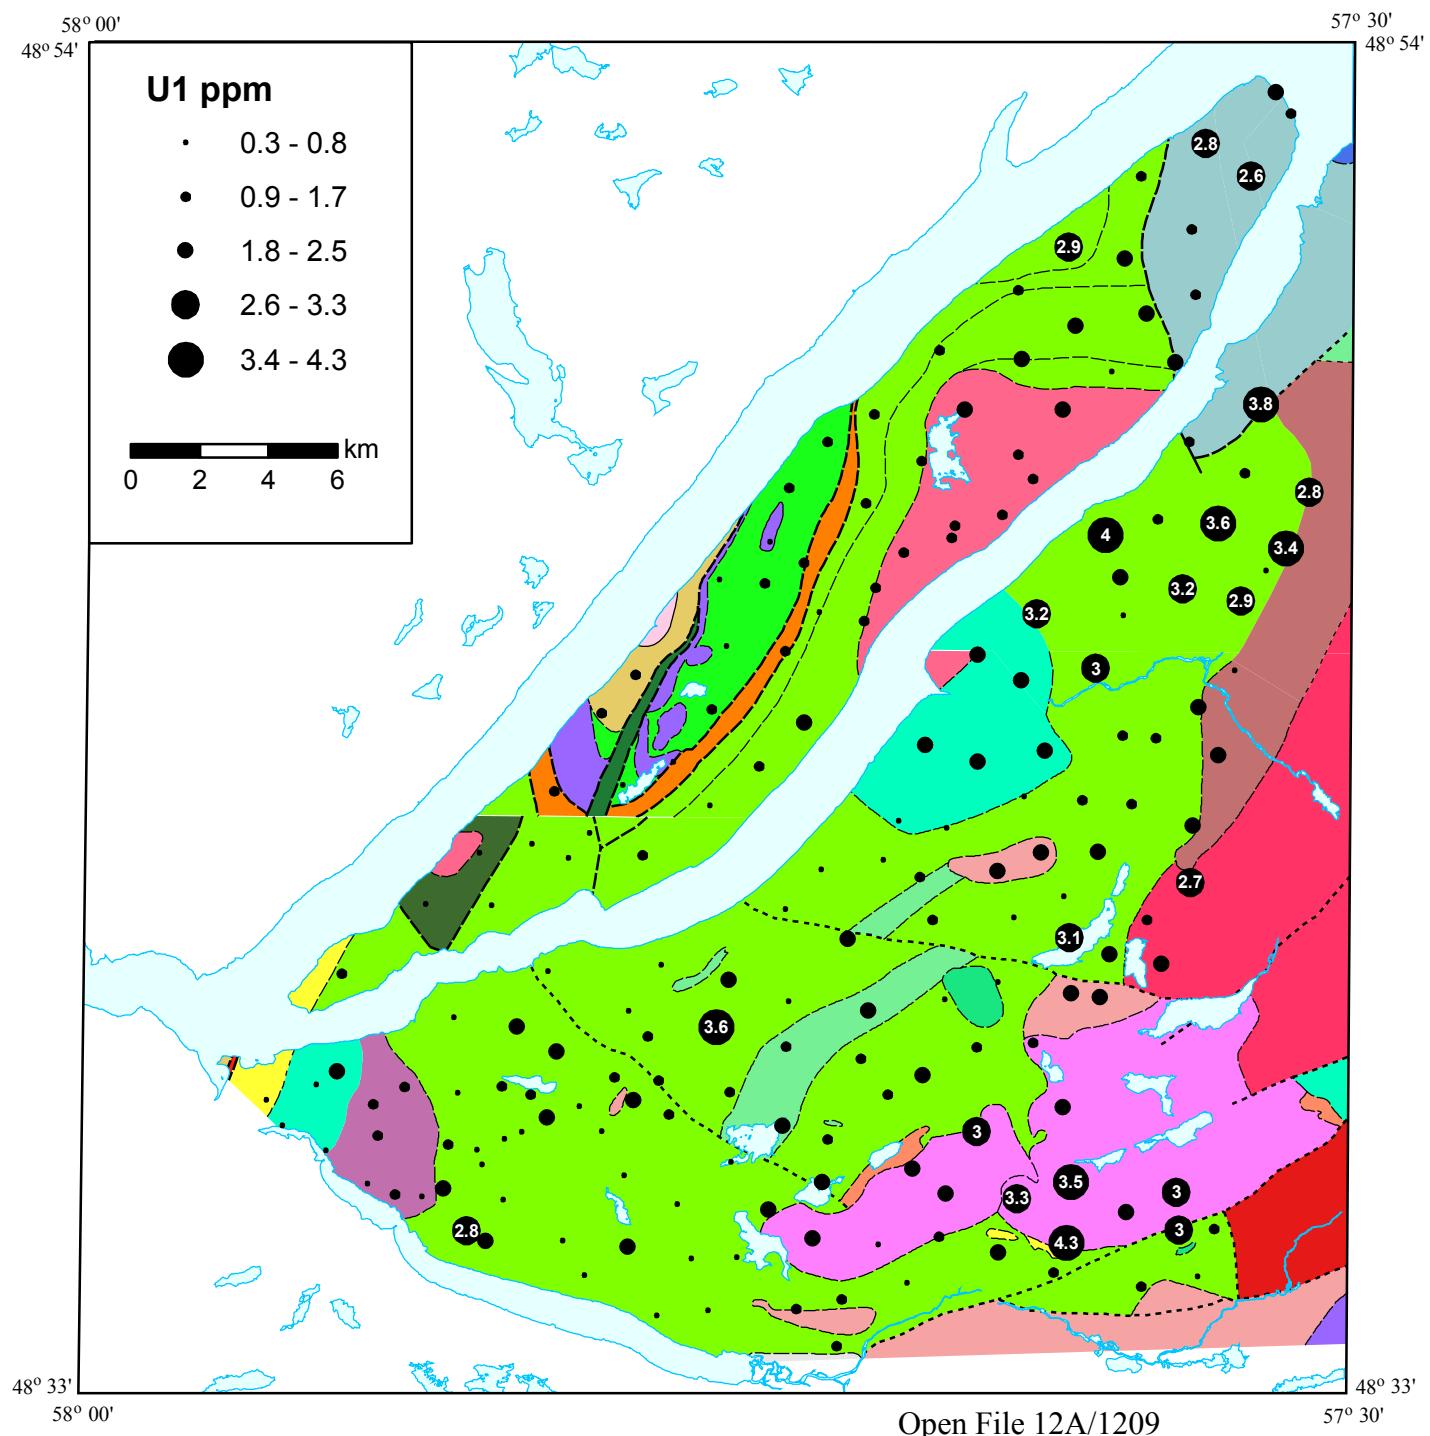

Thanks go out to Stacy Kennedy, Patrick Donovan and Chris Hicks, who provided able field assistance. Gerry Hickey provided logistical support. Universal Helicopters provided access to the area. Chris Finch and the staff of the geochemical laboratory are thanked for their speedy sample processing, and analytical support. Lawson Dickson and Martin Batterson are thanked for reviews of the manuscript.

## Appendix 2: Geochemical Maps

	Page
Distribution of aluminum in till . . . . .	45
Distribution of barium in till . . . . .	46
Distribution of beryllium in till . . . . .	47
Distribution of bromine in till . . . . .	48
Distribution of cadmium in till . . . . .	49
Distribution of calcium in till . . . . .	50
Distribution of cerium in till . . . . .	51
Distribution of cesium in till . . . . .	52
Distribution of chromium in till . . . . .	53
Distribution of cobalt in till . . . . .	54
Distribution of dysprosium in till . . . . .	55
Distribution of europium in till . . . . .	56
Distribution of hafnium in till . . . . .	57
Distribution of iron in till . . . . .	58
Distribution of lanthanum in till . . . . .	59
Distribution of lead in till . . . . .	60
Distribution of lithium in till . . . . .	61
Distribution of loss-on-ignition in till . . . . .	62
Distribution of lutetium in till . . . . .	63
Distribution of magnesium in till . . . . .	64
Distribution of manganese in till . . . . .	65
Distribution of molybdenum in till . . . . .	66
Distribution of neodymium in till . . . . .	67
Distribution of niobium in till . . . . .	68
Distribution of phosphorous in till . . . . .	69
Distribution of potassium in till . . . . .	70
Distribution of rubidium in till . . . . .	71
Distribution of samarium in till . . . . .	72
Distribution of scandium in till . . . . .	73
Distribution of sodium in till . . . . .	74
Distribution of strontium in till . . . . .	75
Distribution of tantalum in till . . . . .	76
Distribution of terbium in till . . . . .	77
Distribution of thorium in till . . . . .	78
Distribution of titanium in till . . . . .	79
Distribution of vanadium in till . . . . .	80
Distribution of ytterbium in till . . . . .	81
Distribution of yttrium in till . . . . .	82
Distribution of zinc in till . . . . .	83
Distribution of zirconium in till . . . . .	84

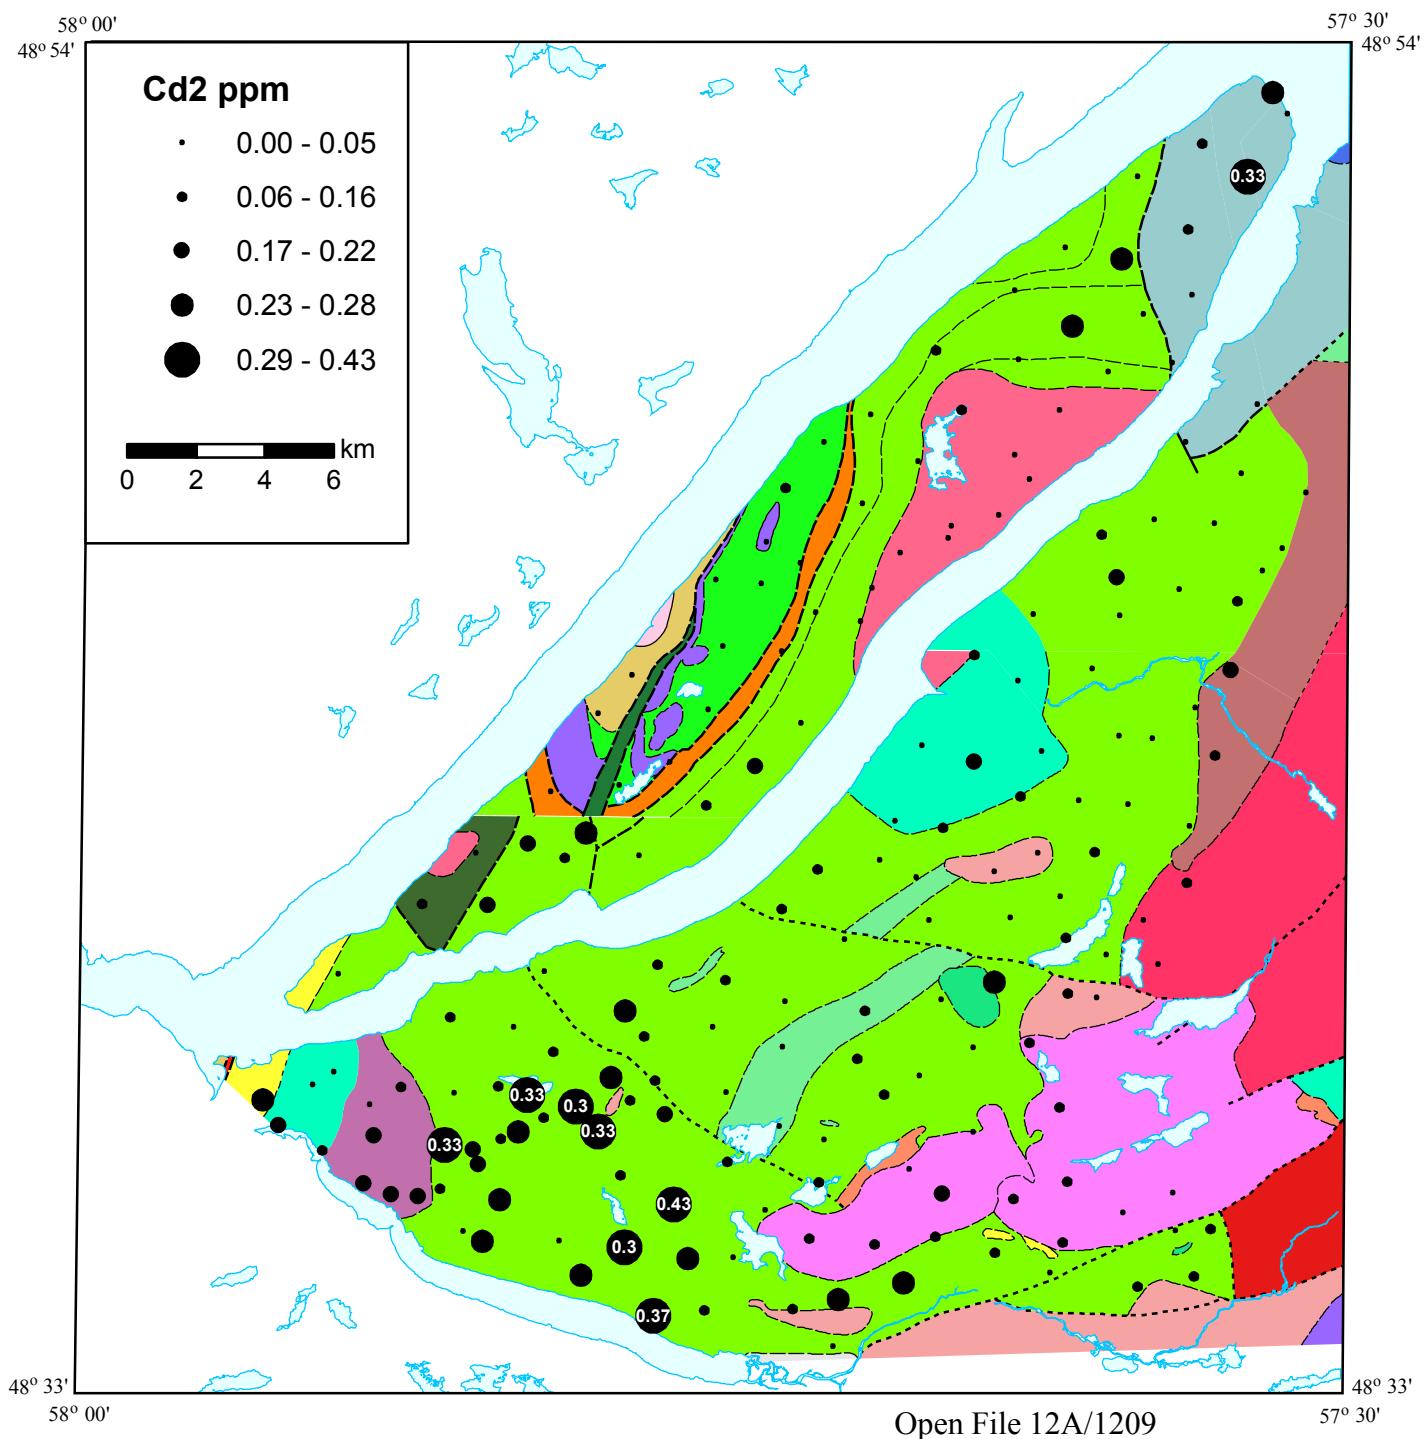

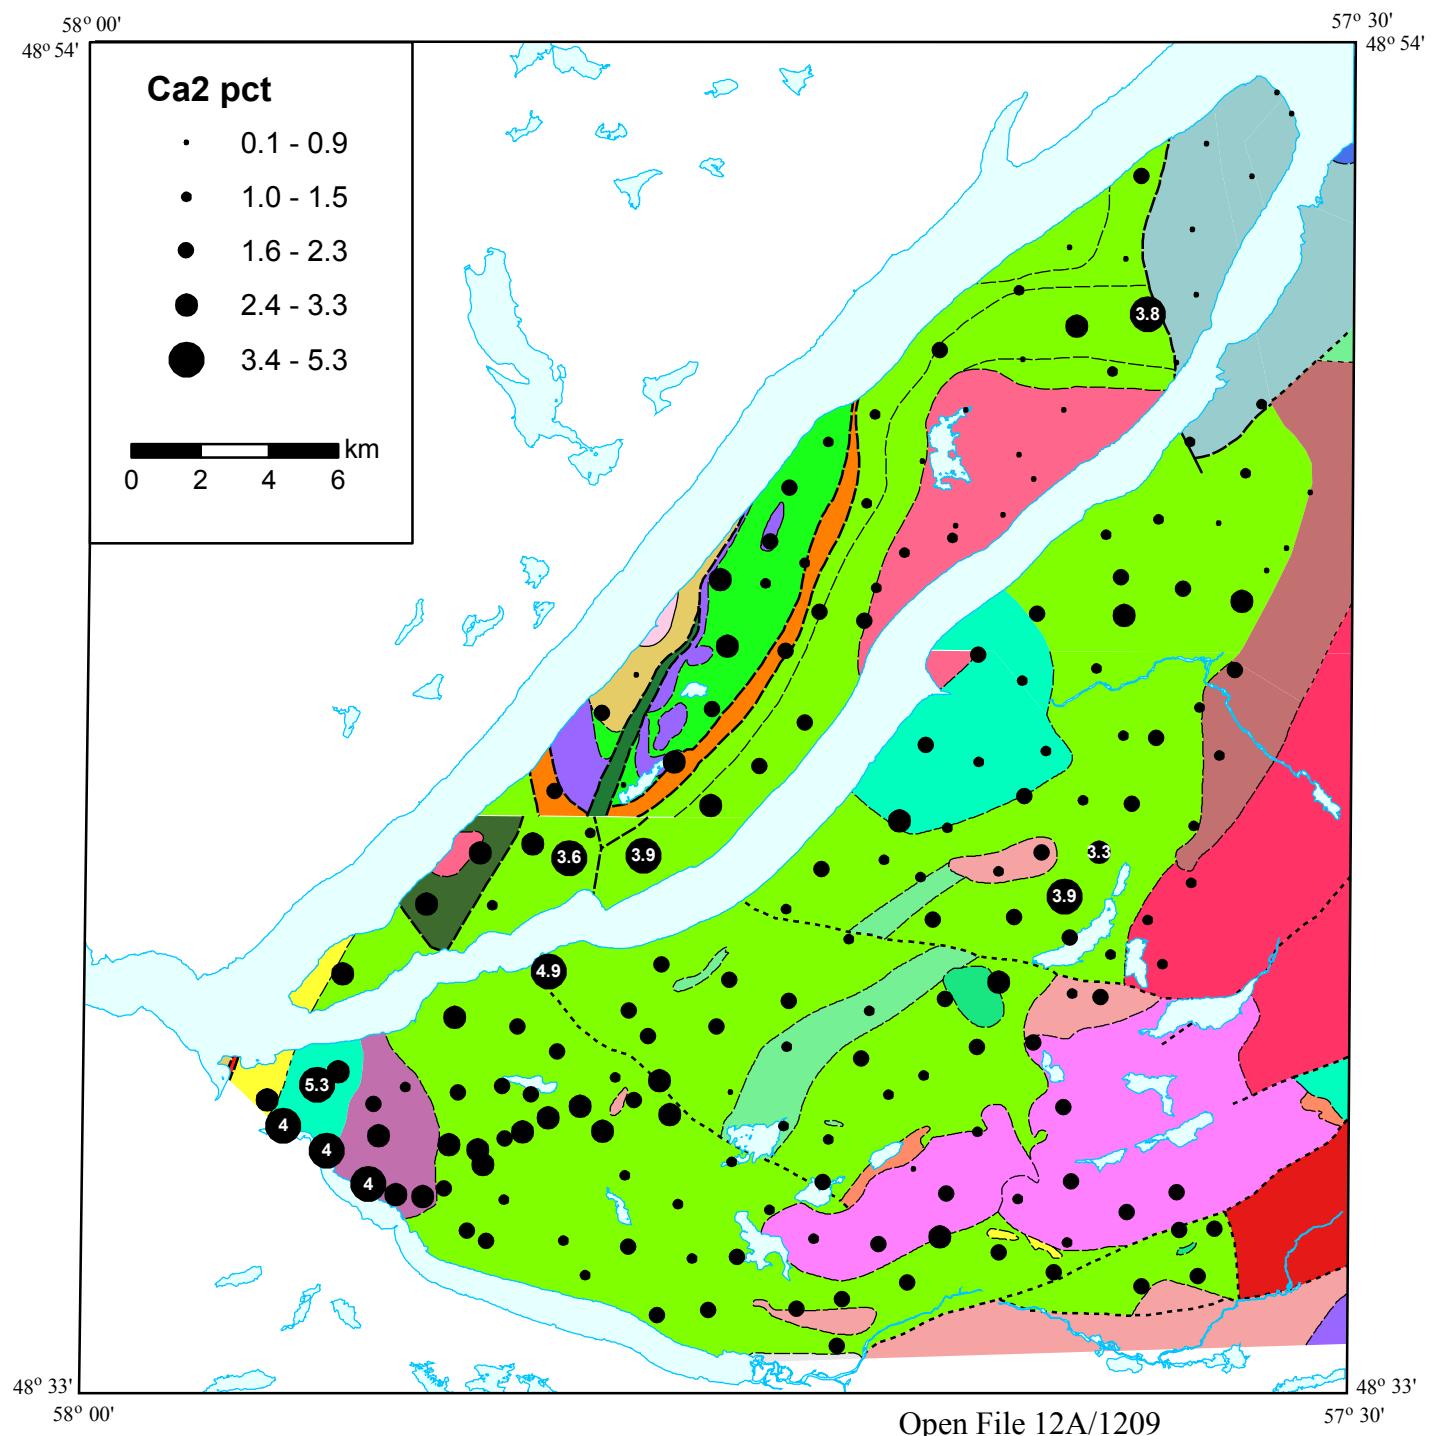

*Distribution of barium in till.*

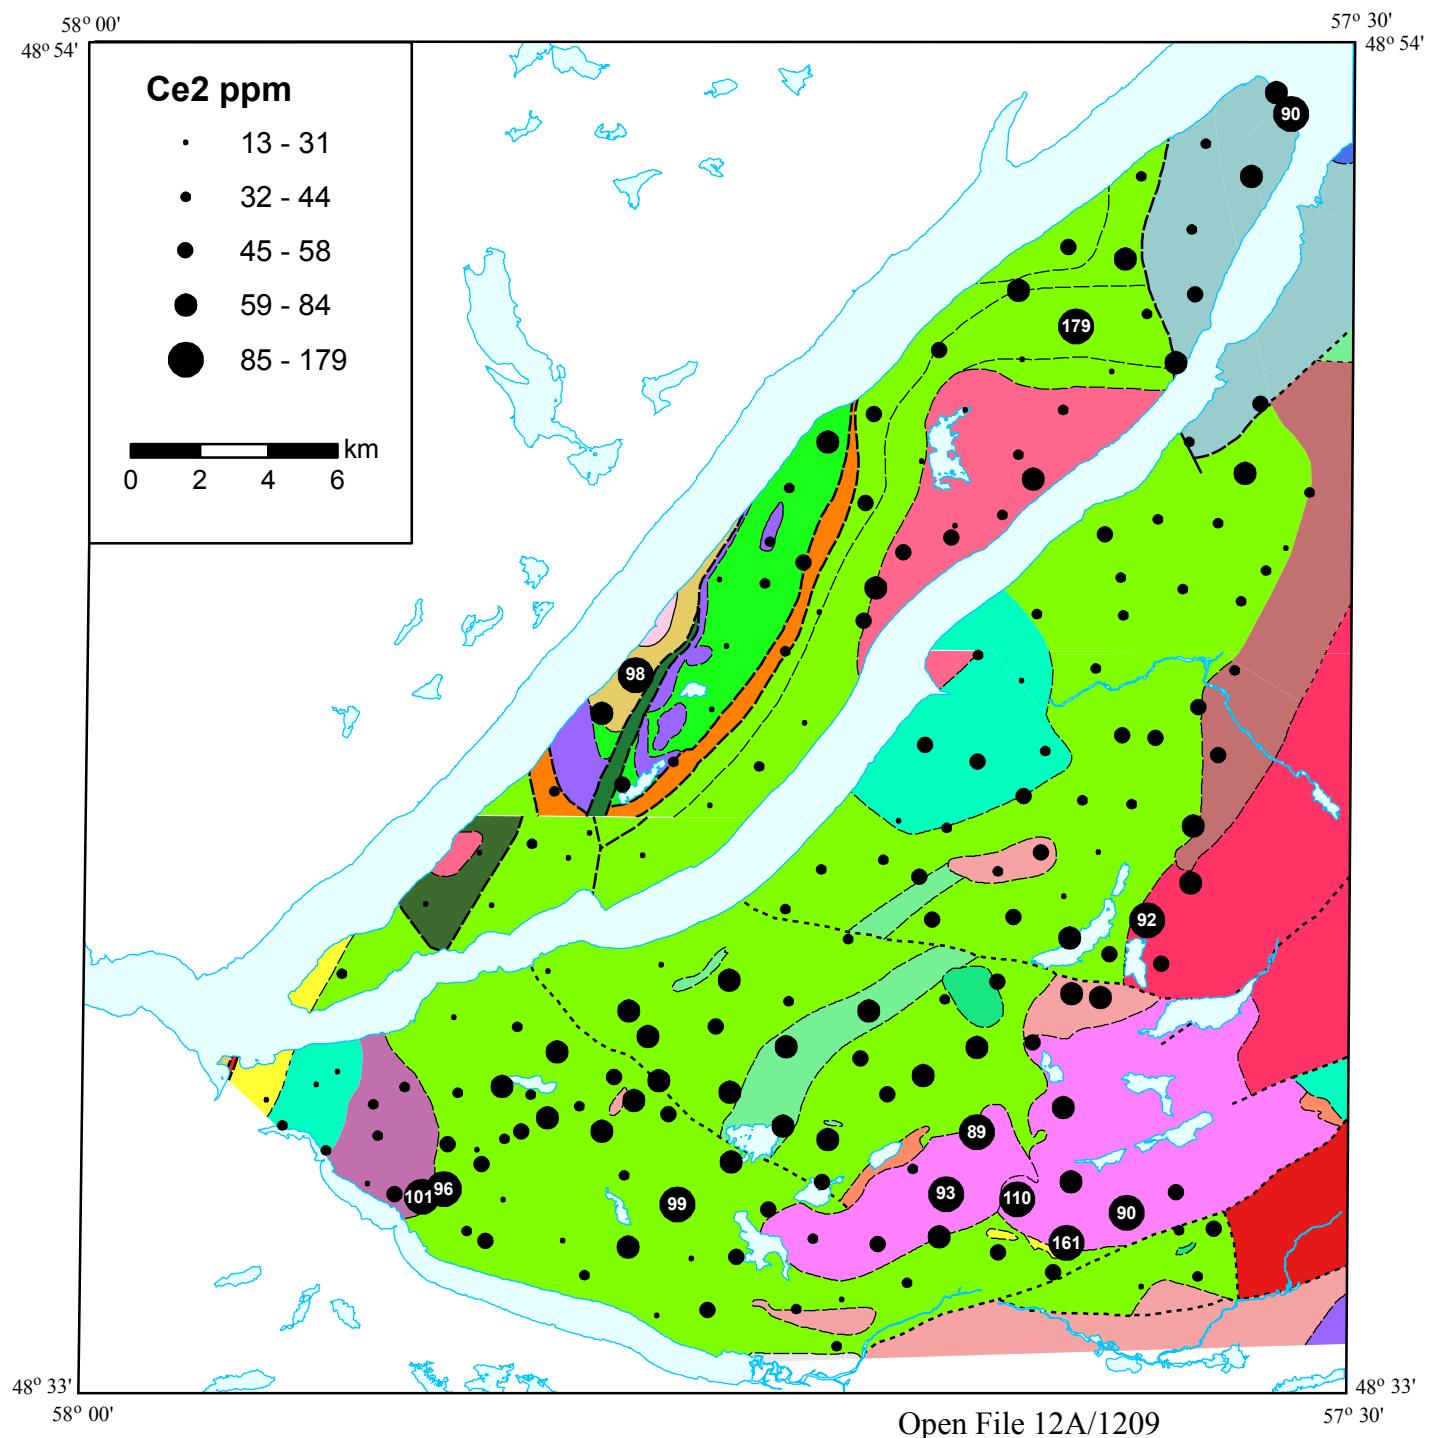

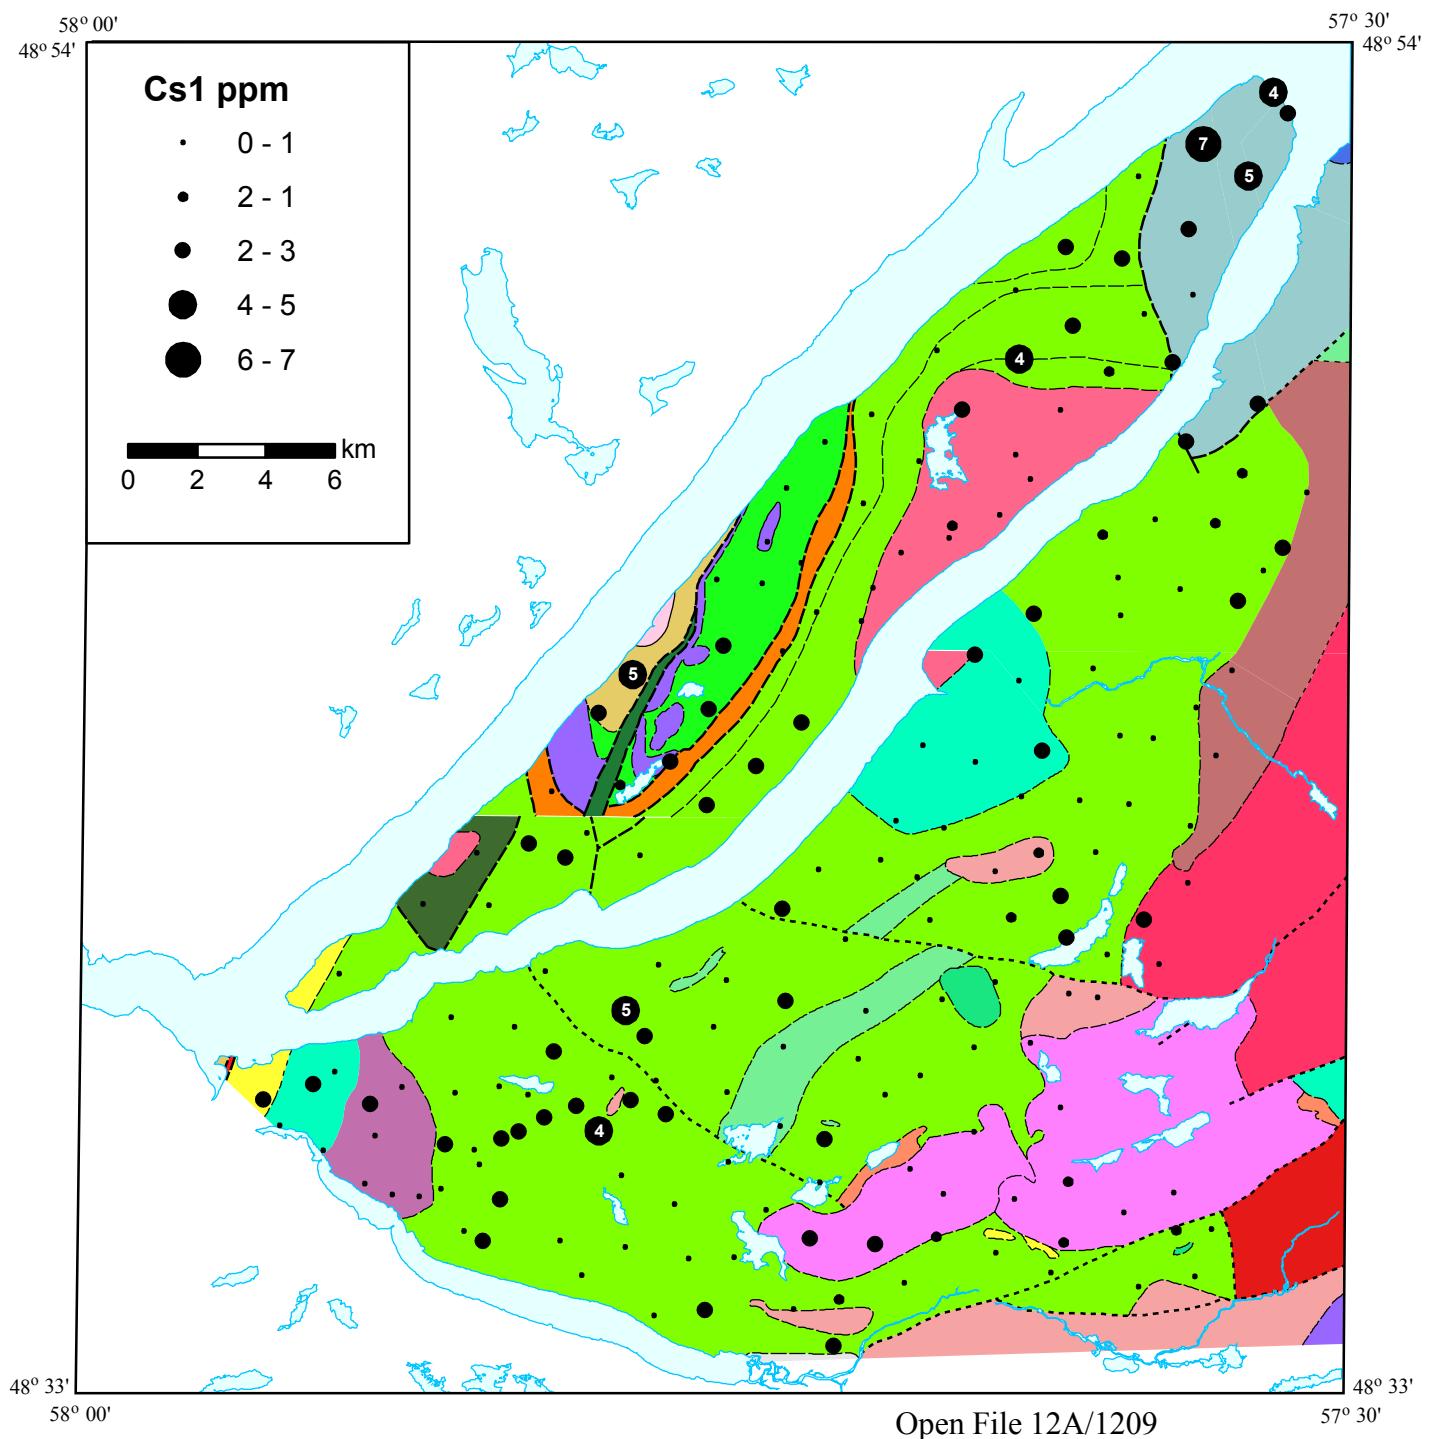

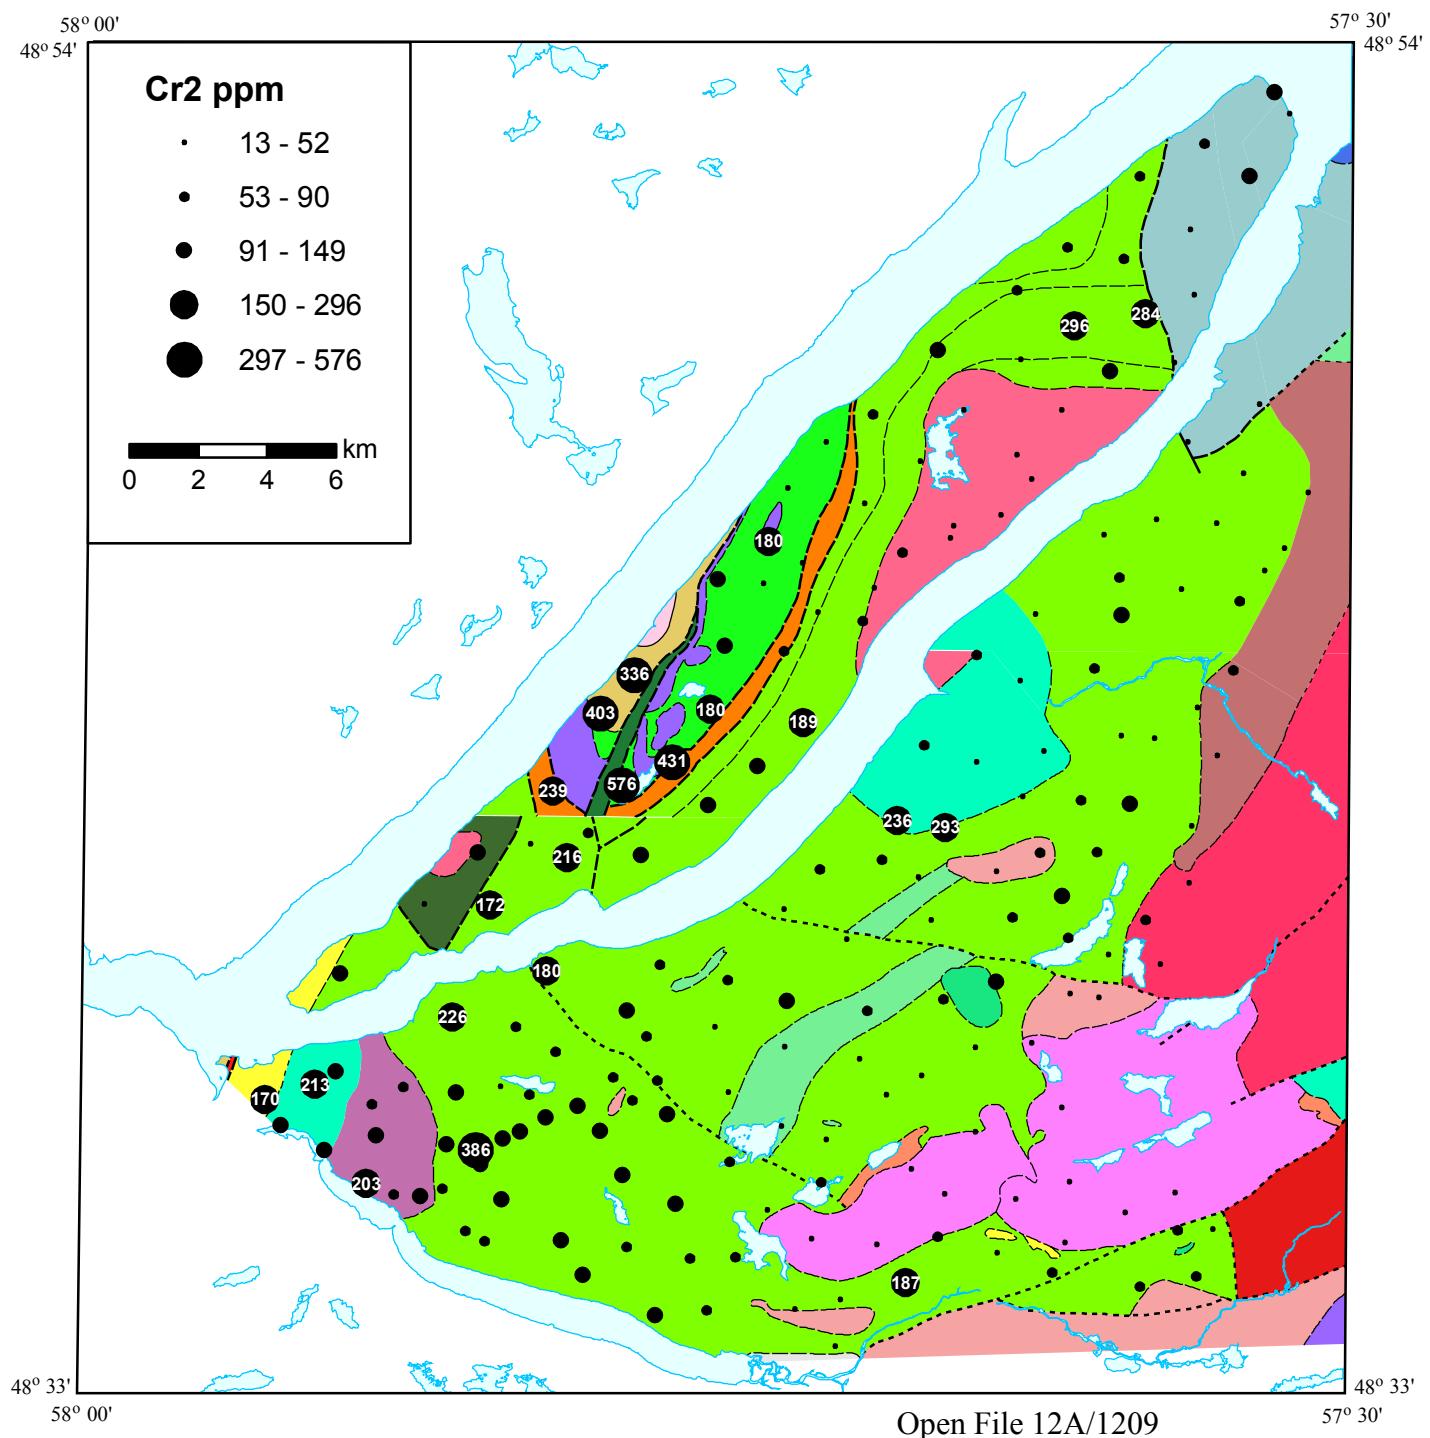

*Distribution of calcium in till.*

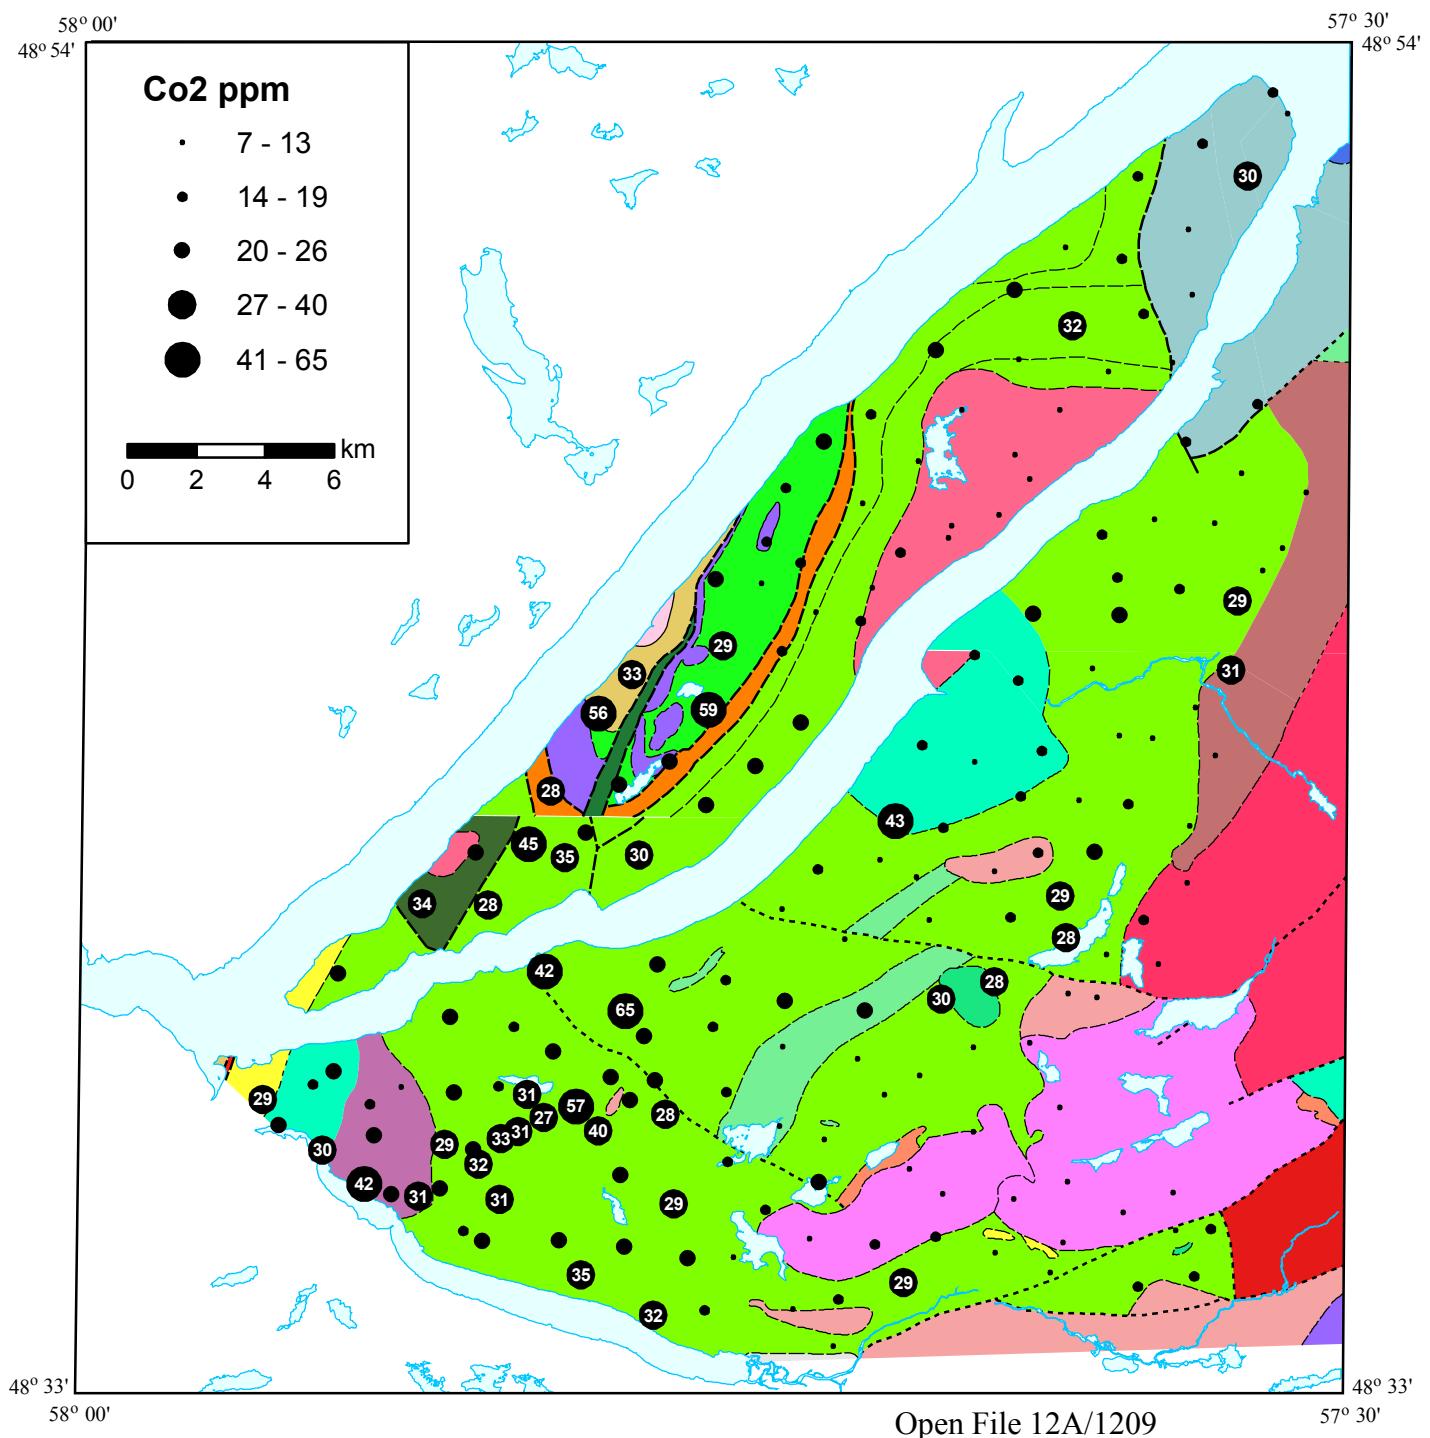

*Distribution of cerium in till.*

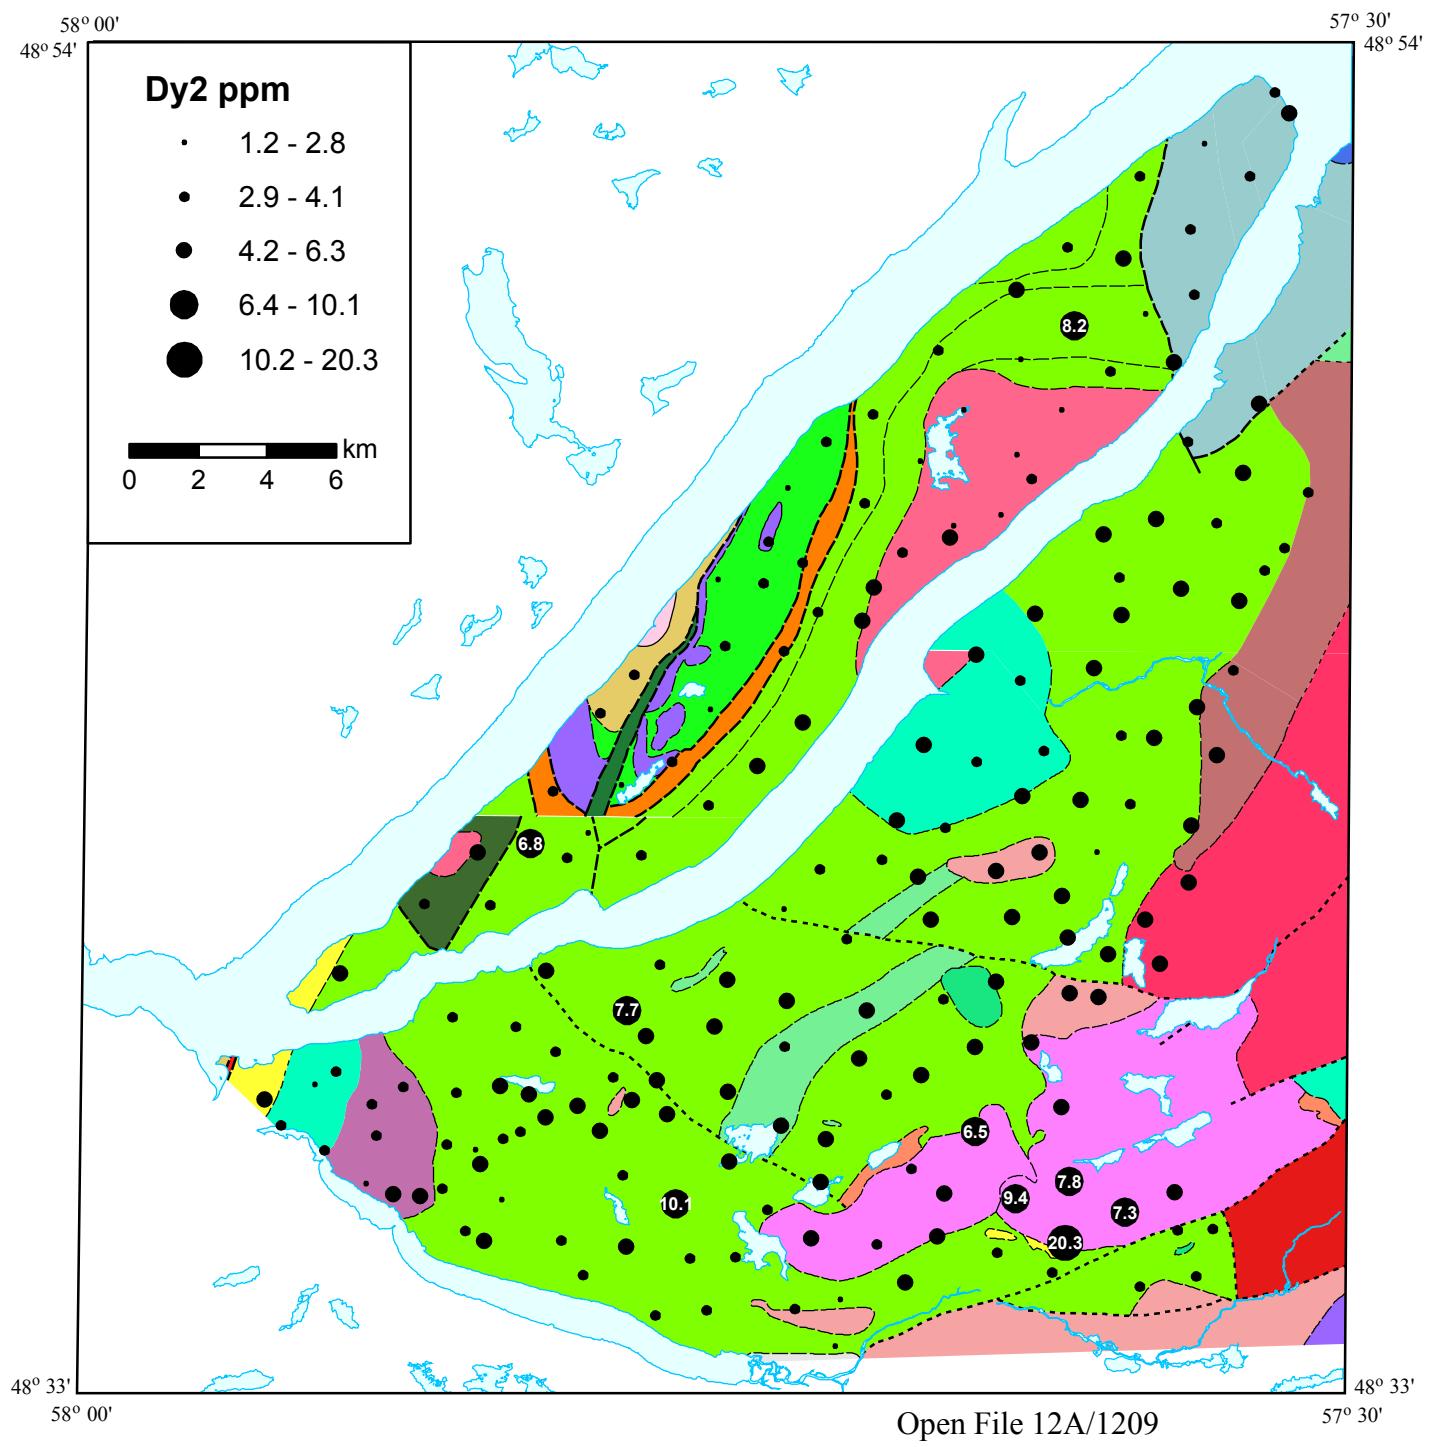

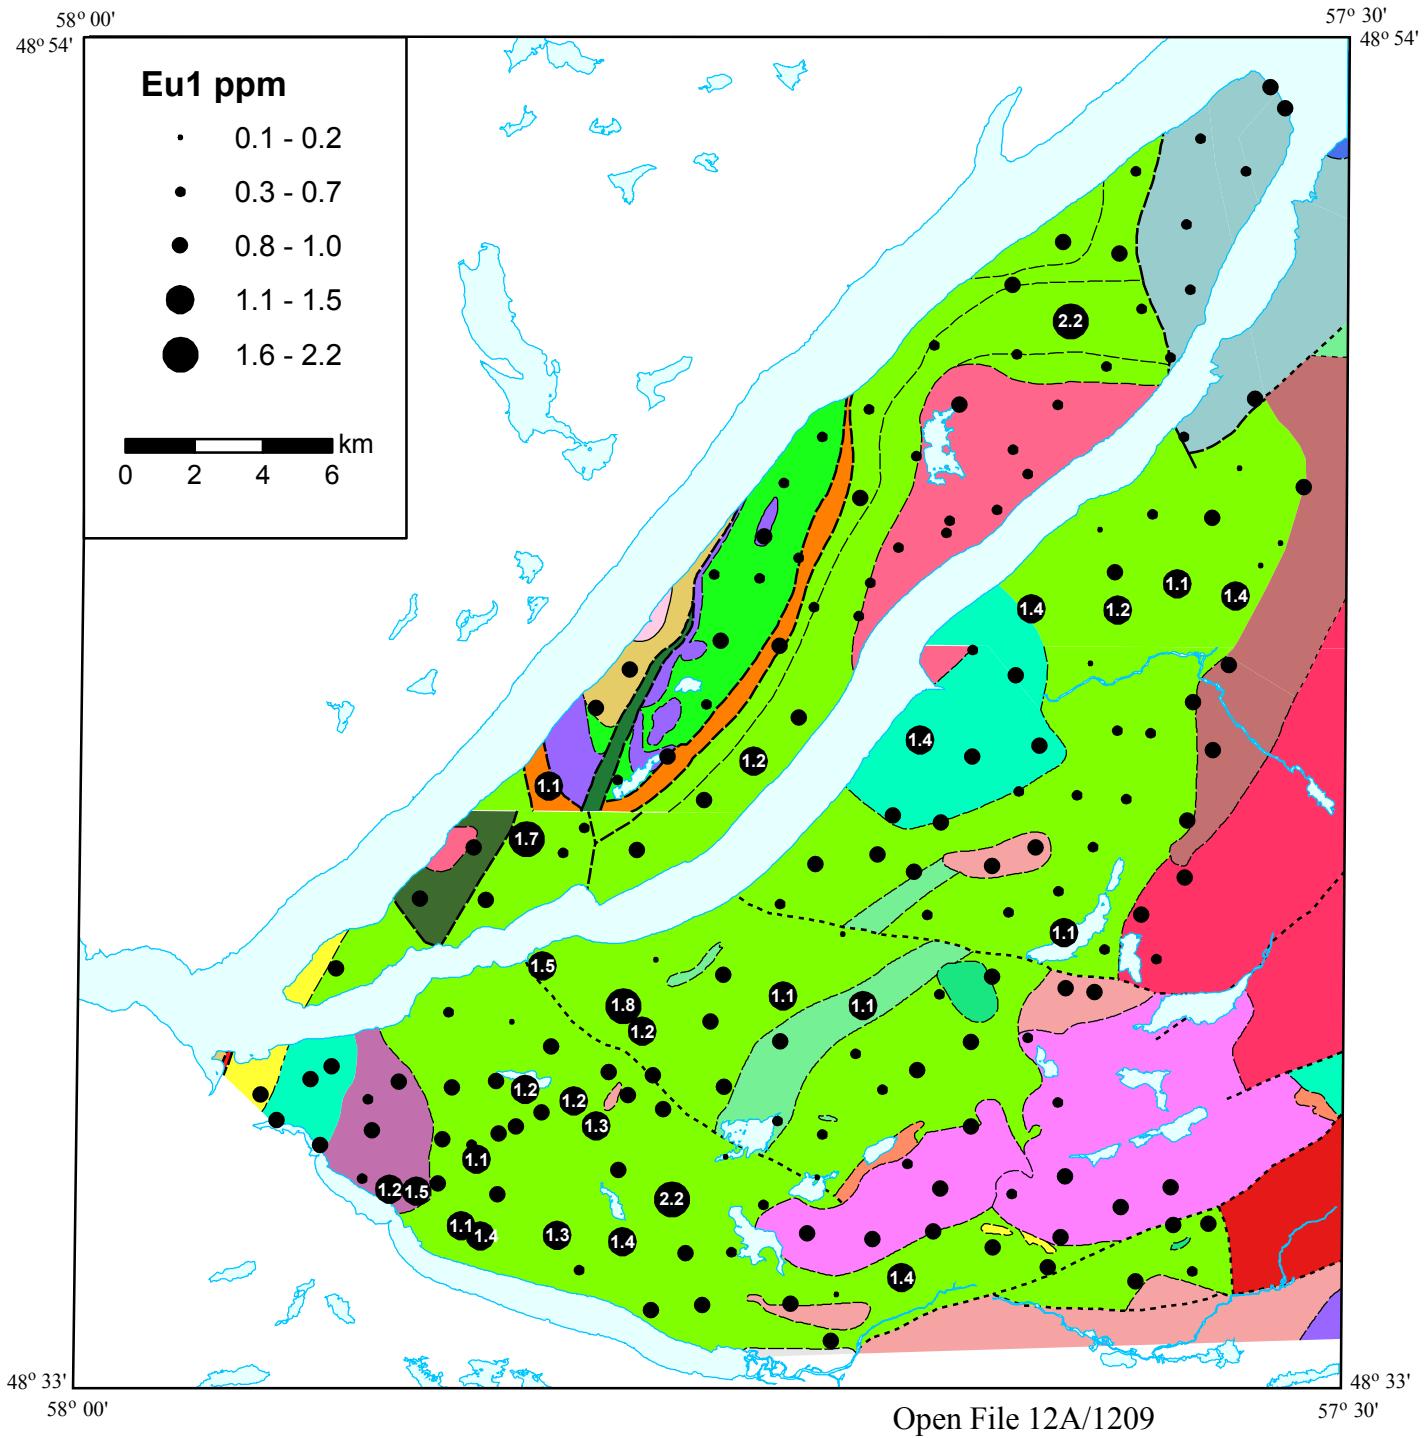

*Distribution of chromium in till.*

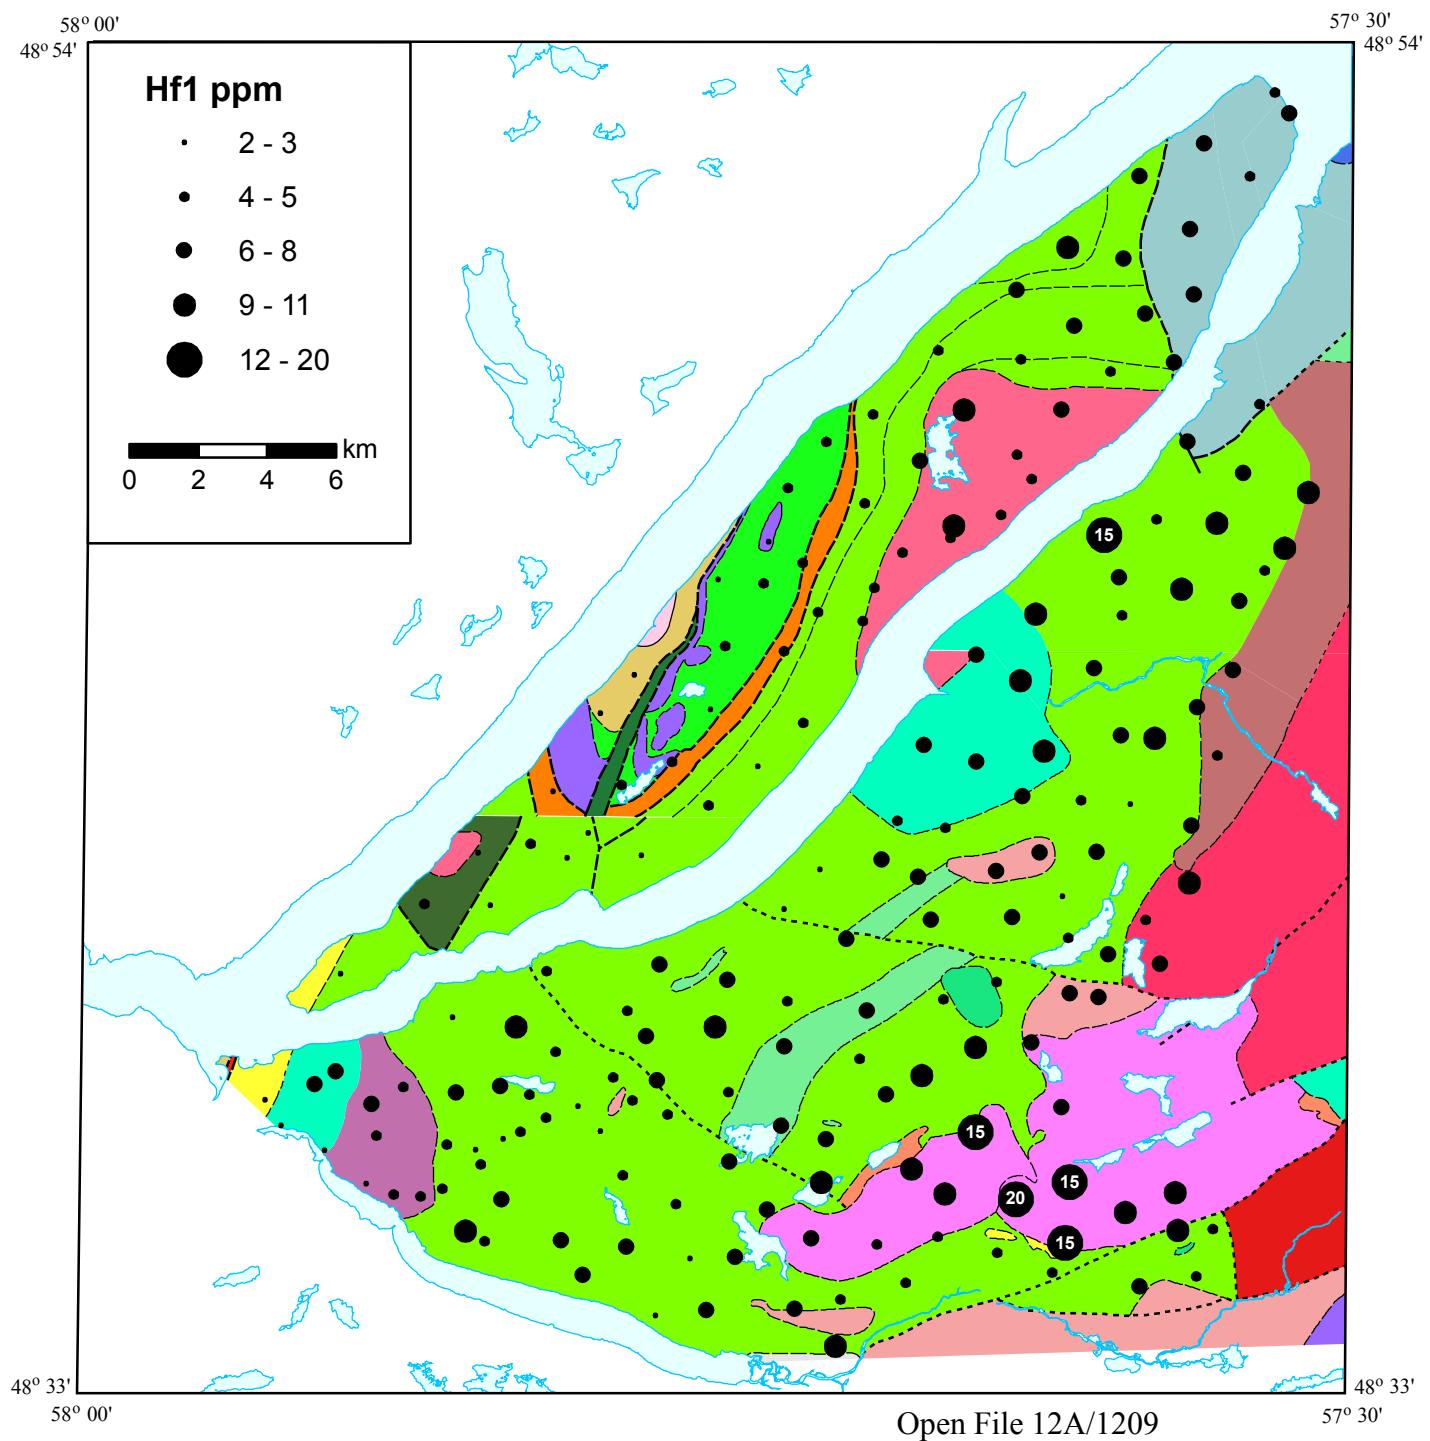

*Distribution of cobalt in till.*

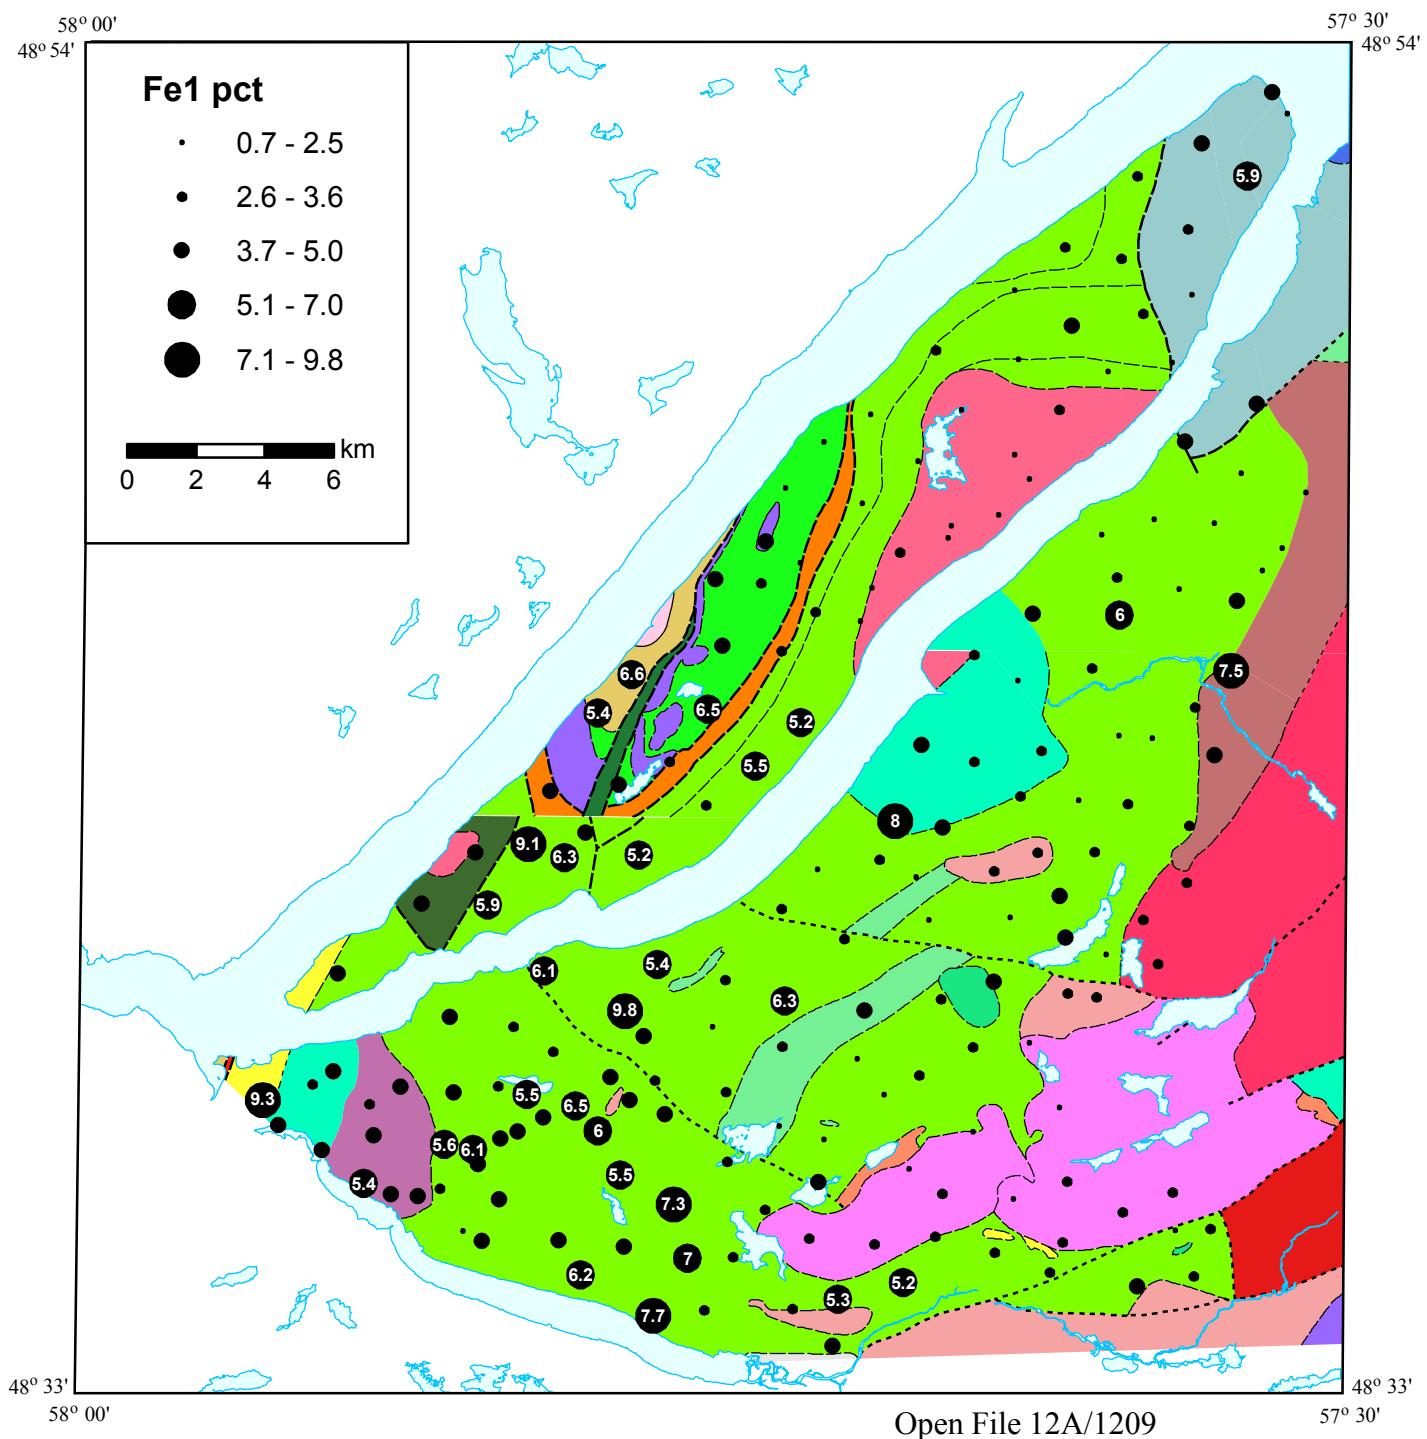

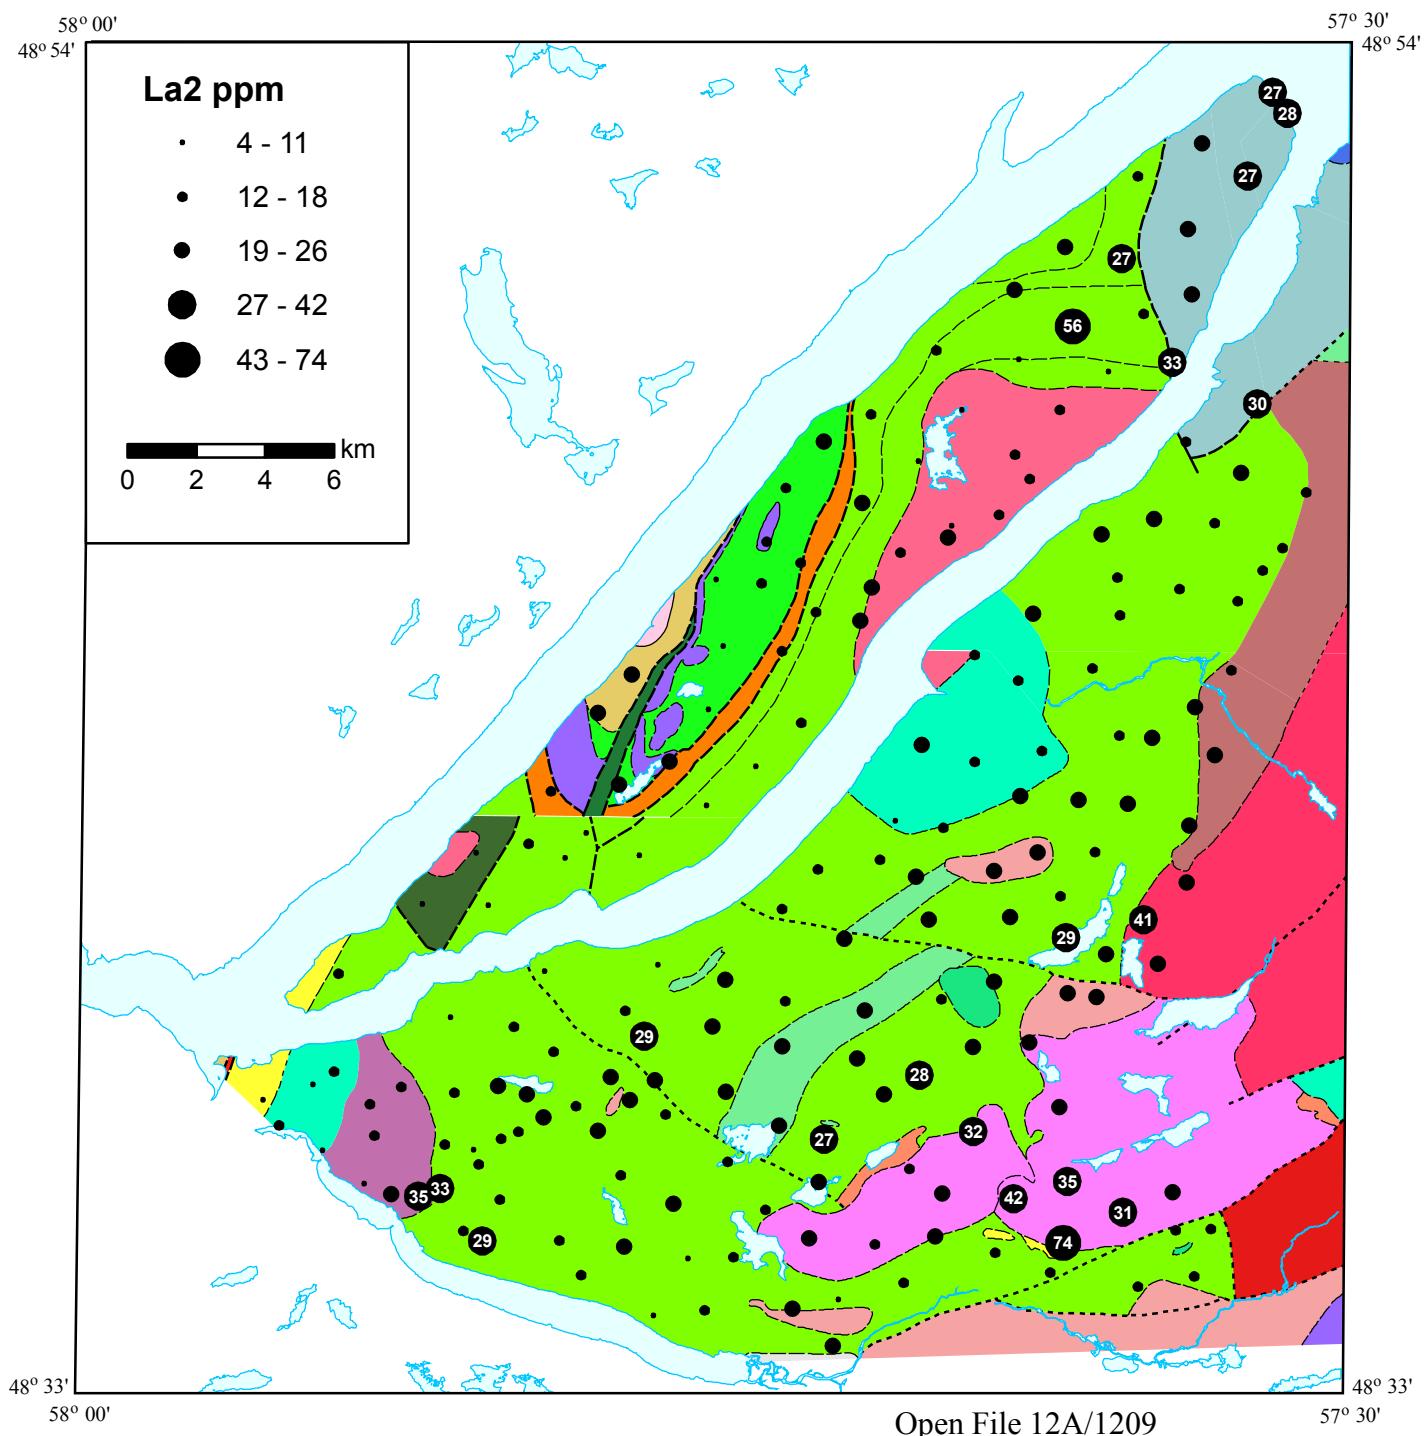

### *Distribution of europium in till.*

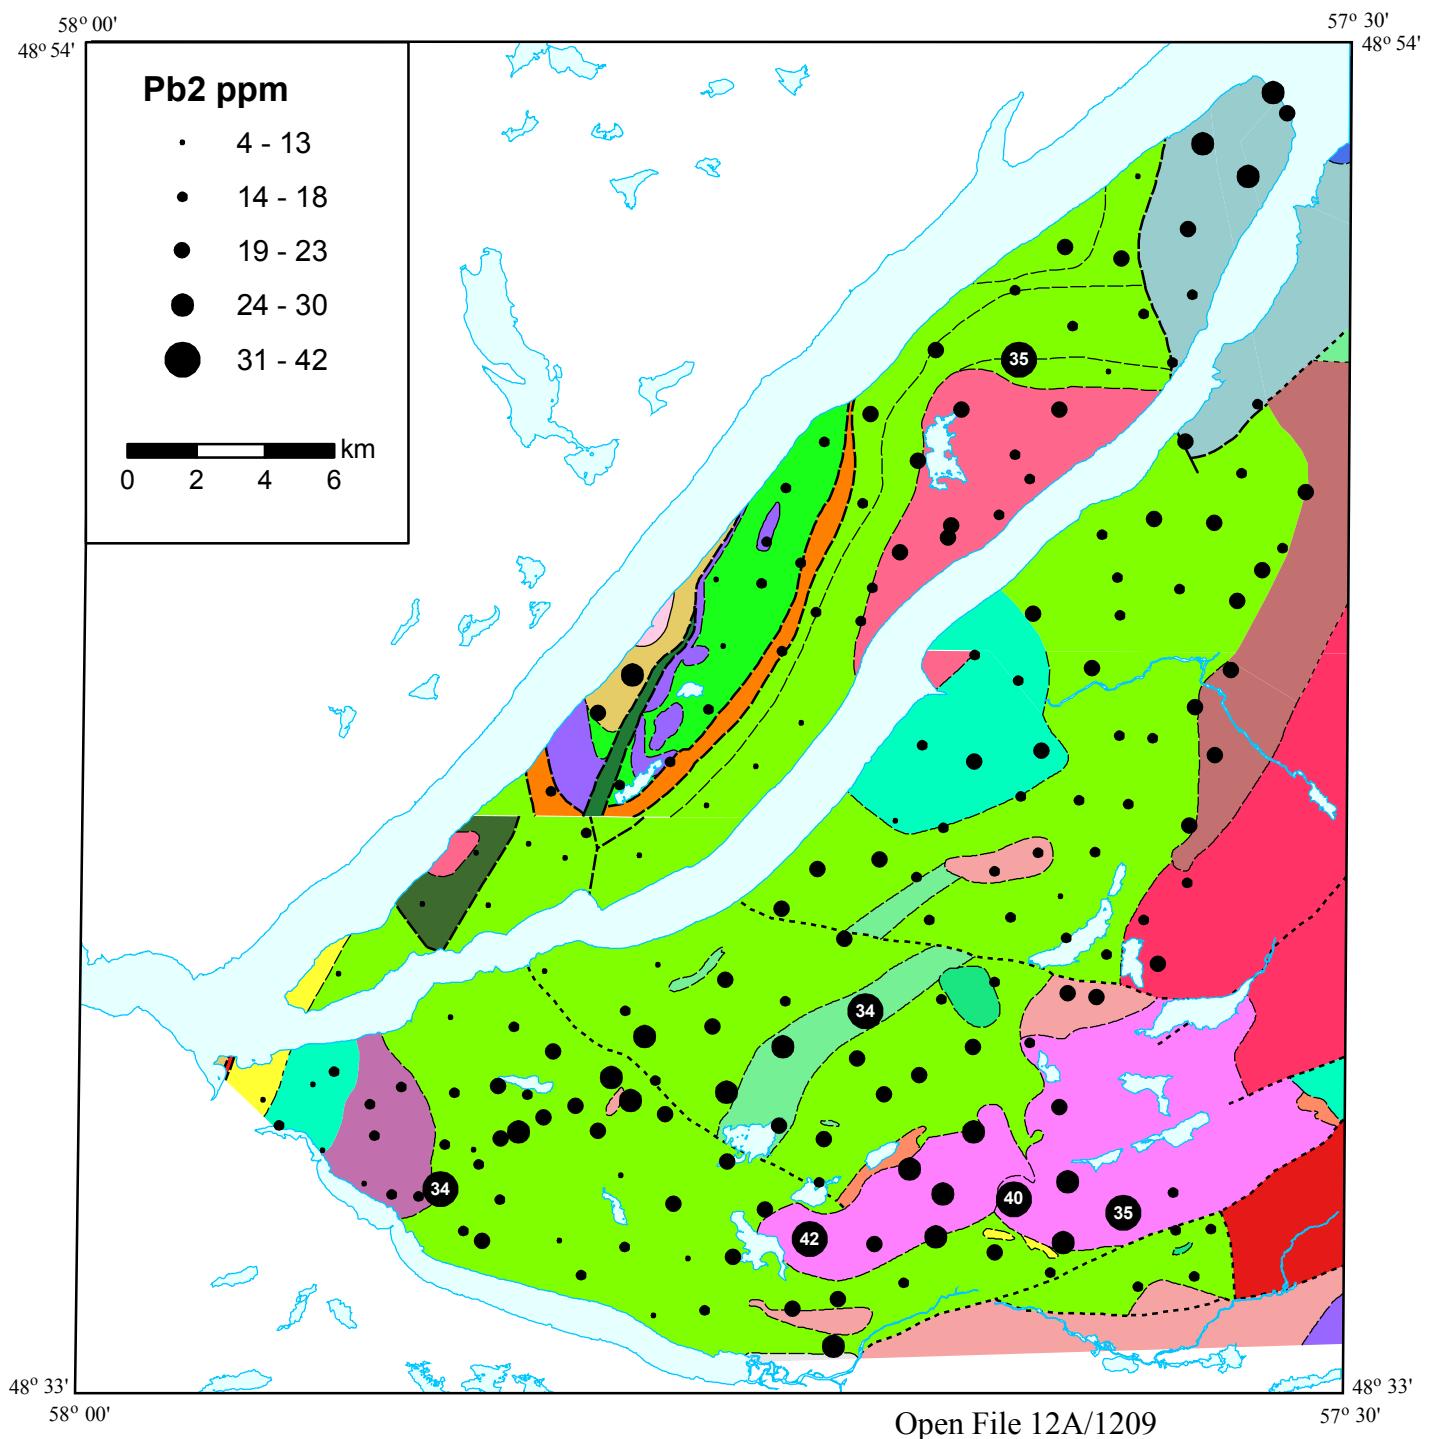

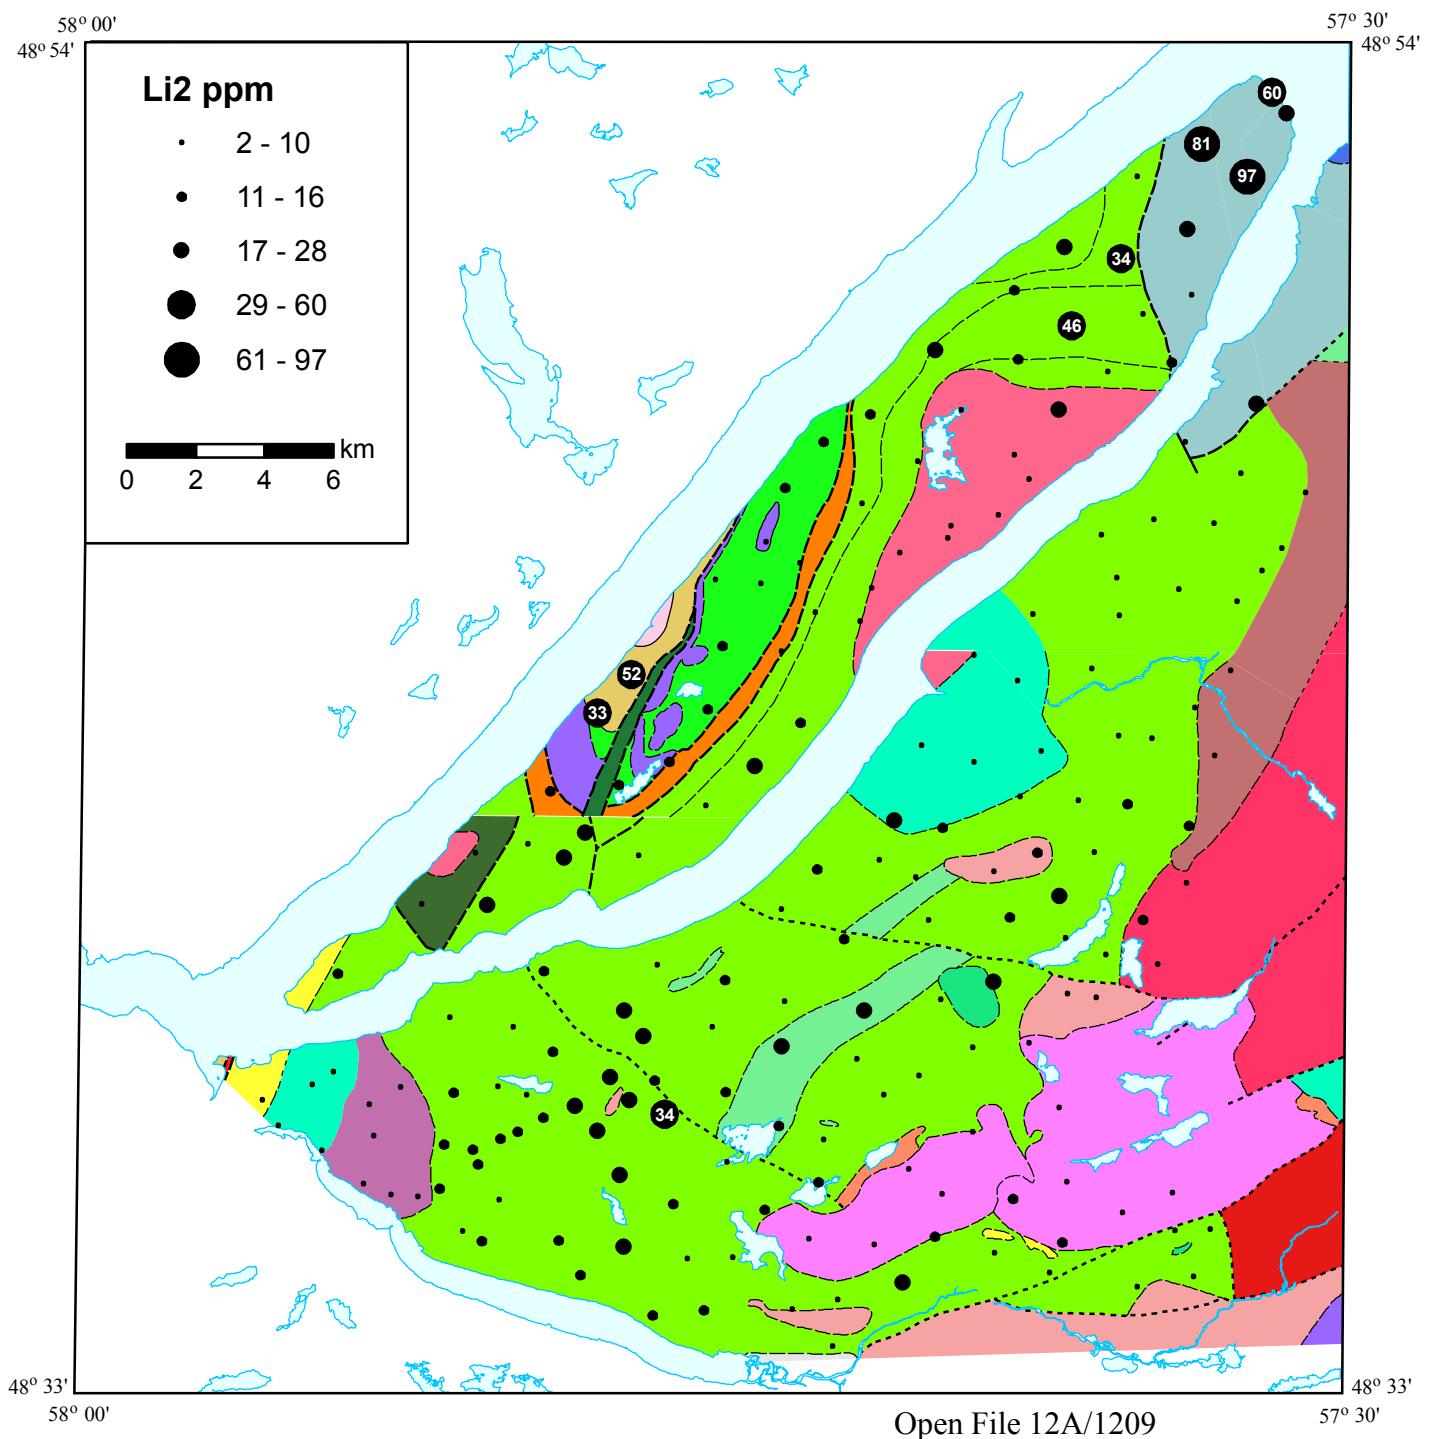

*Distribution of hafnium in till.*

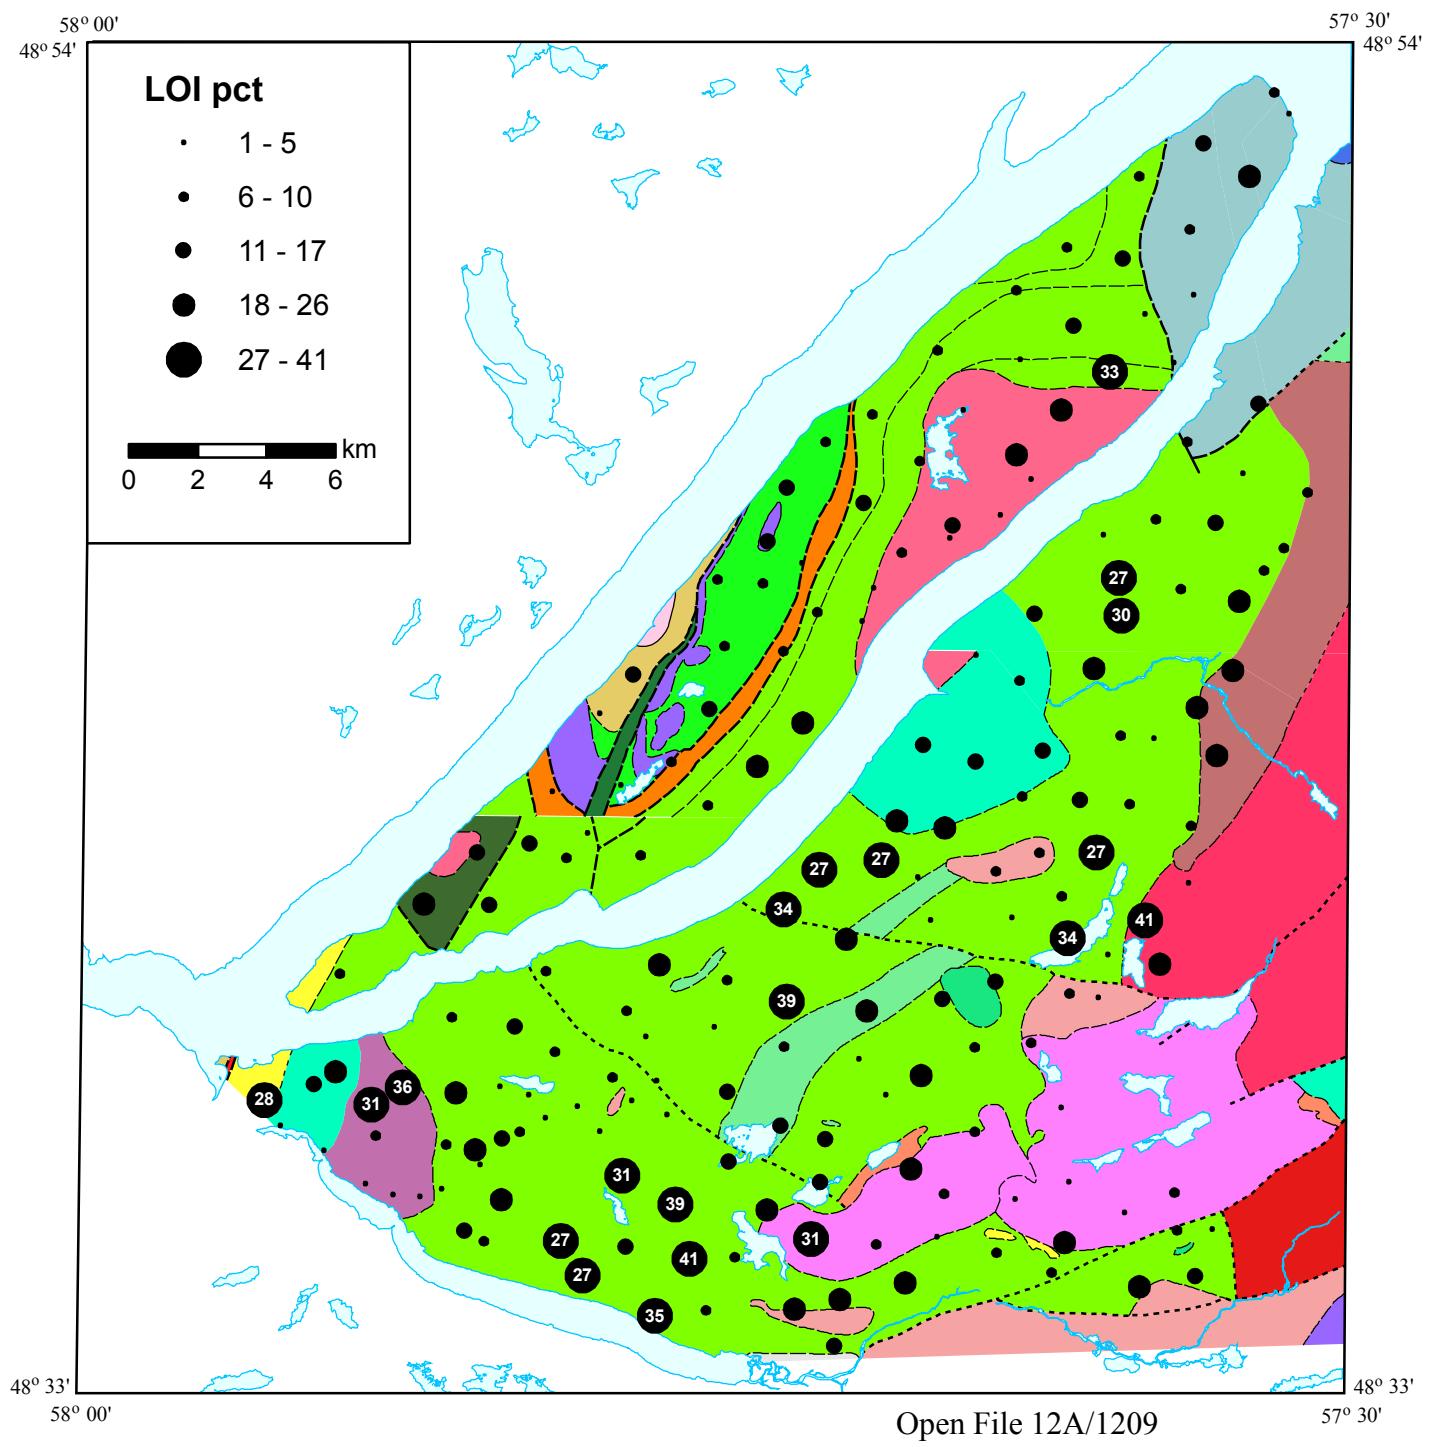

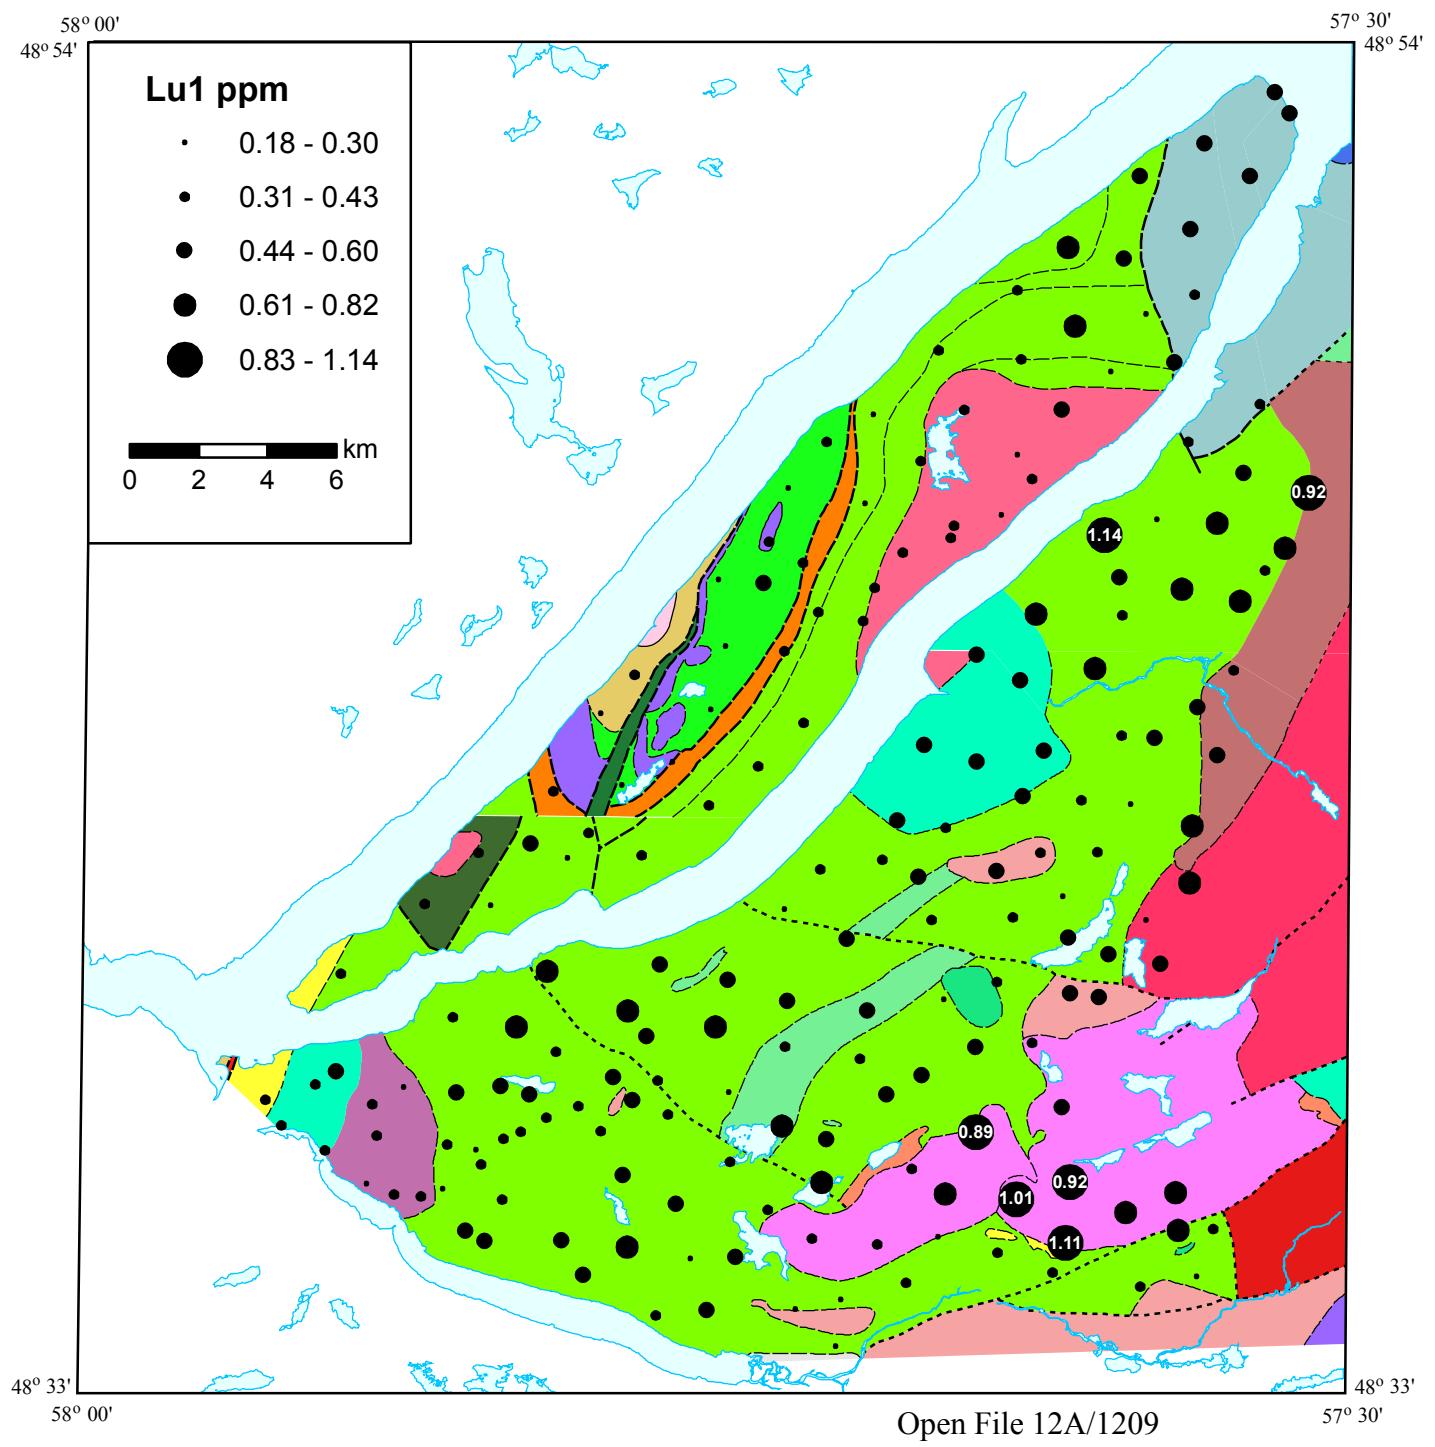

*Distribution of lanthanum in till.*

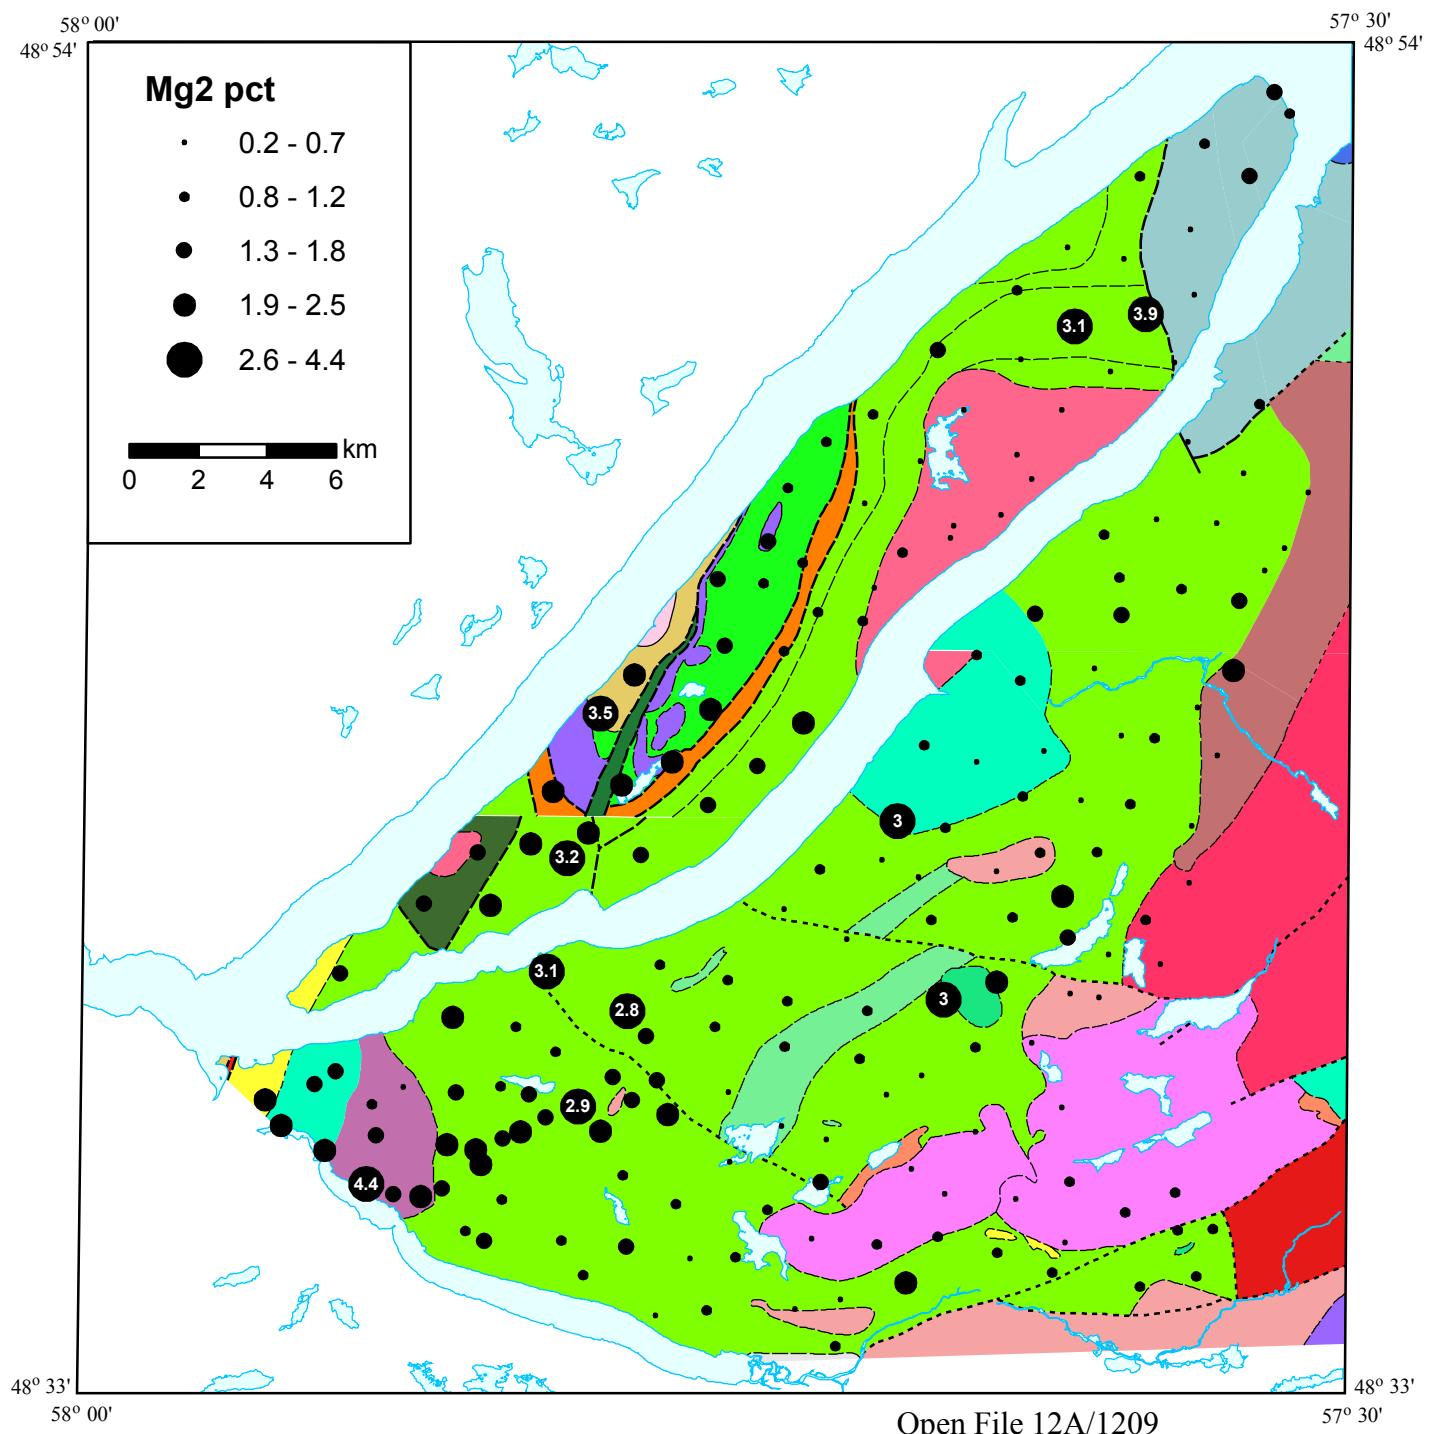

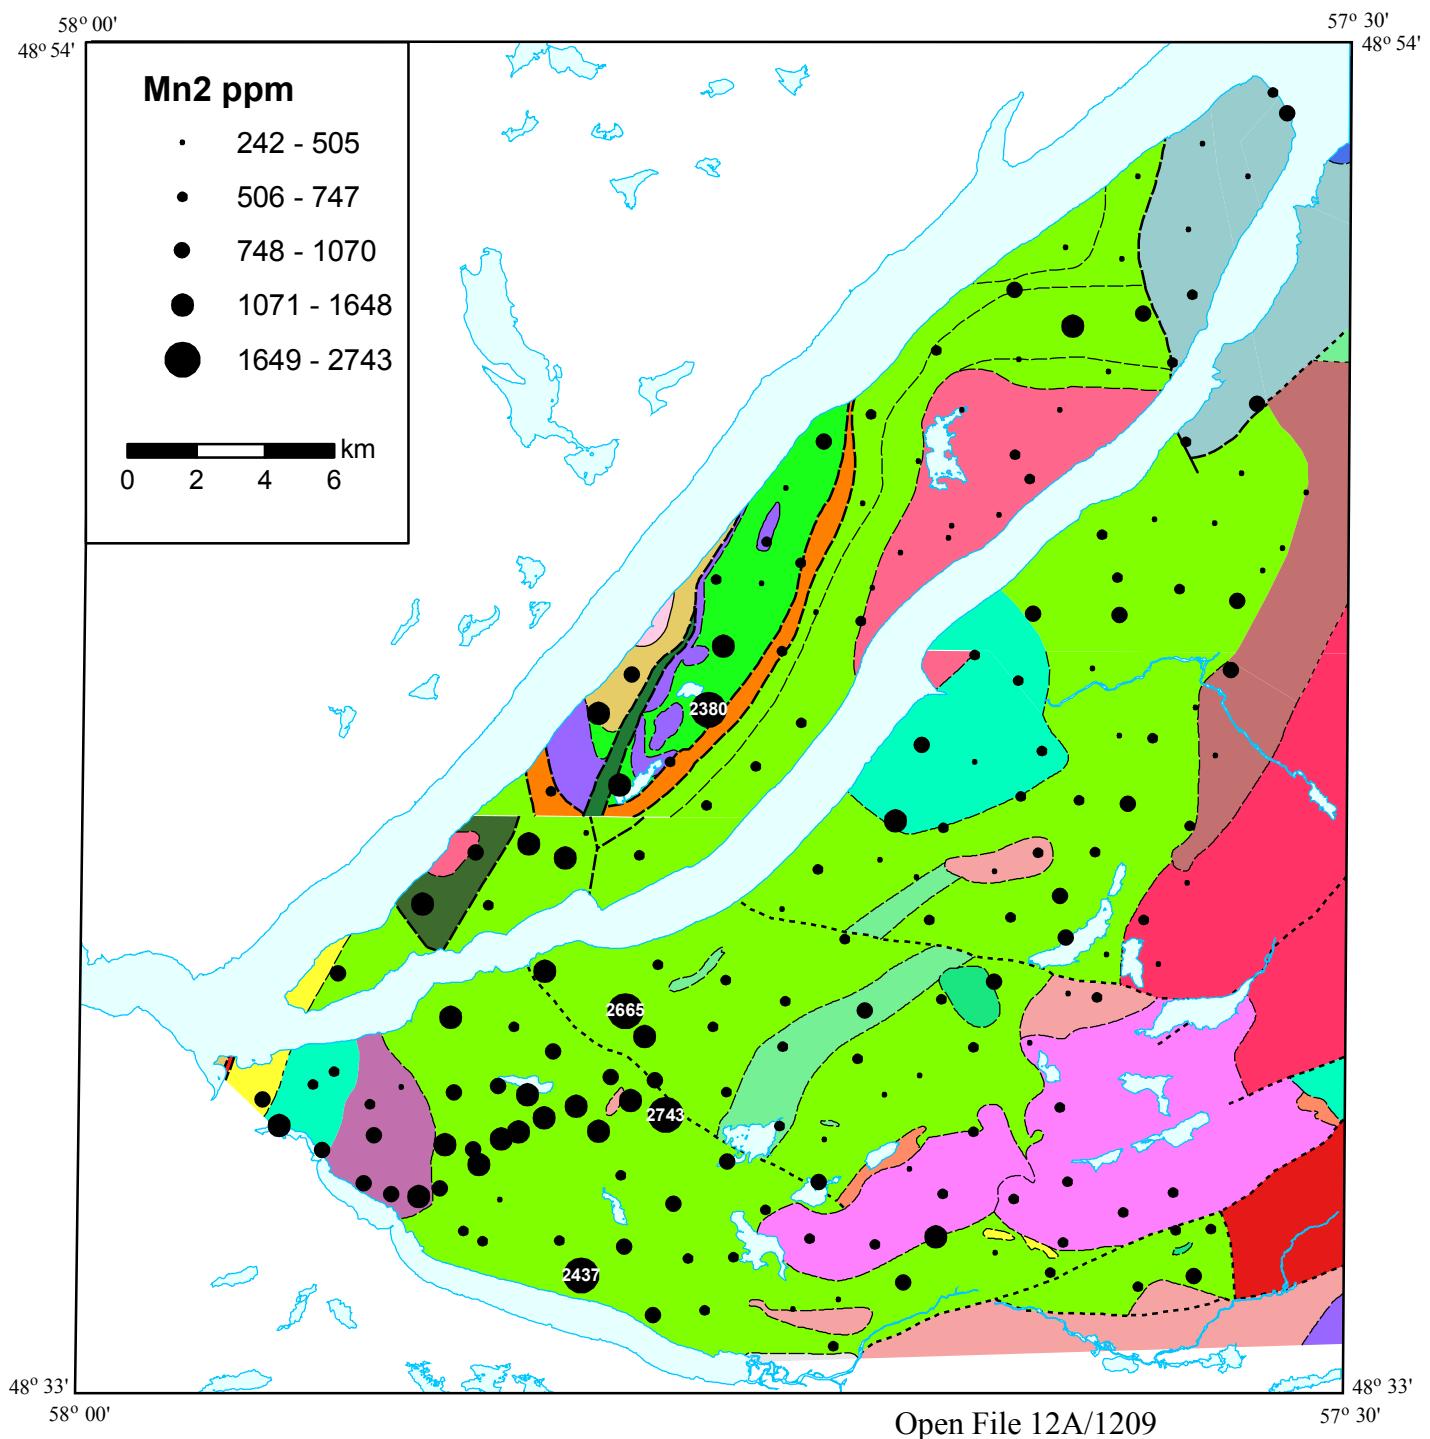

*Distribution of lithium in till.*

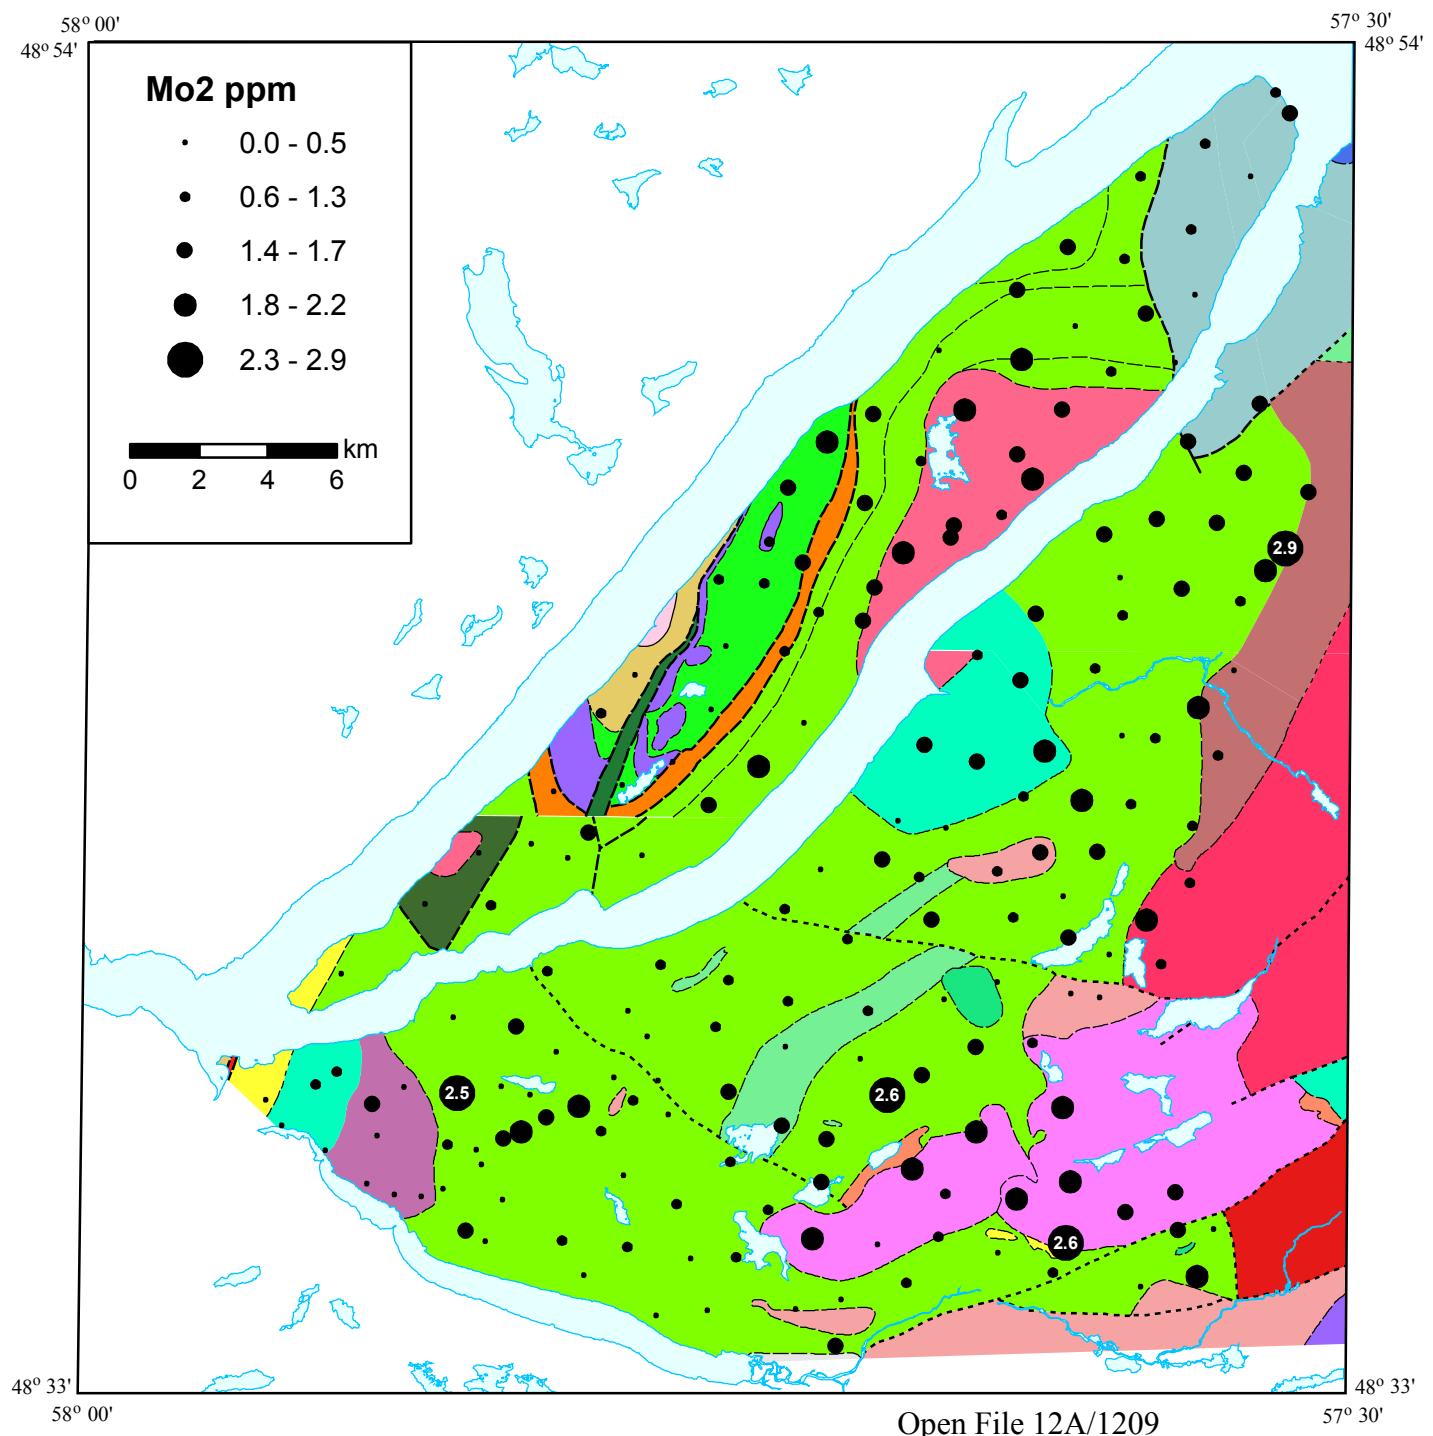

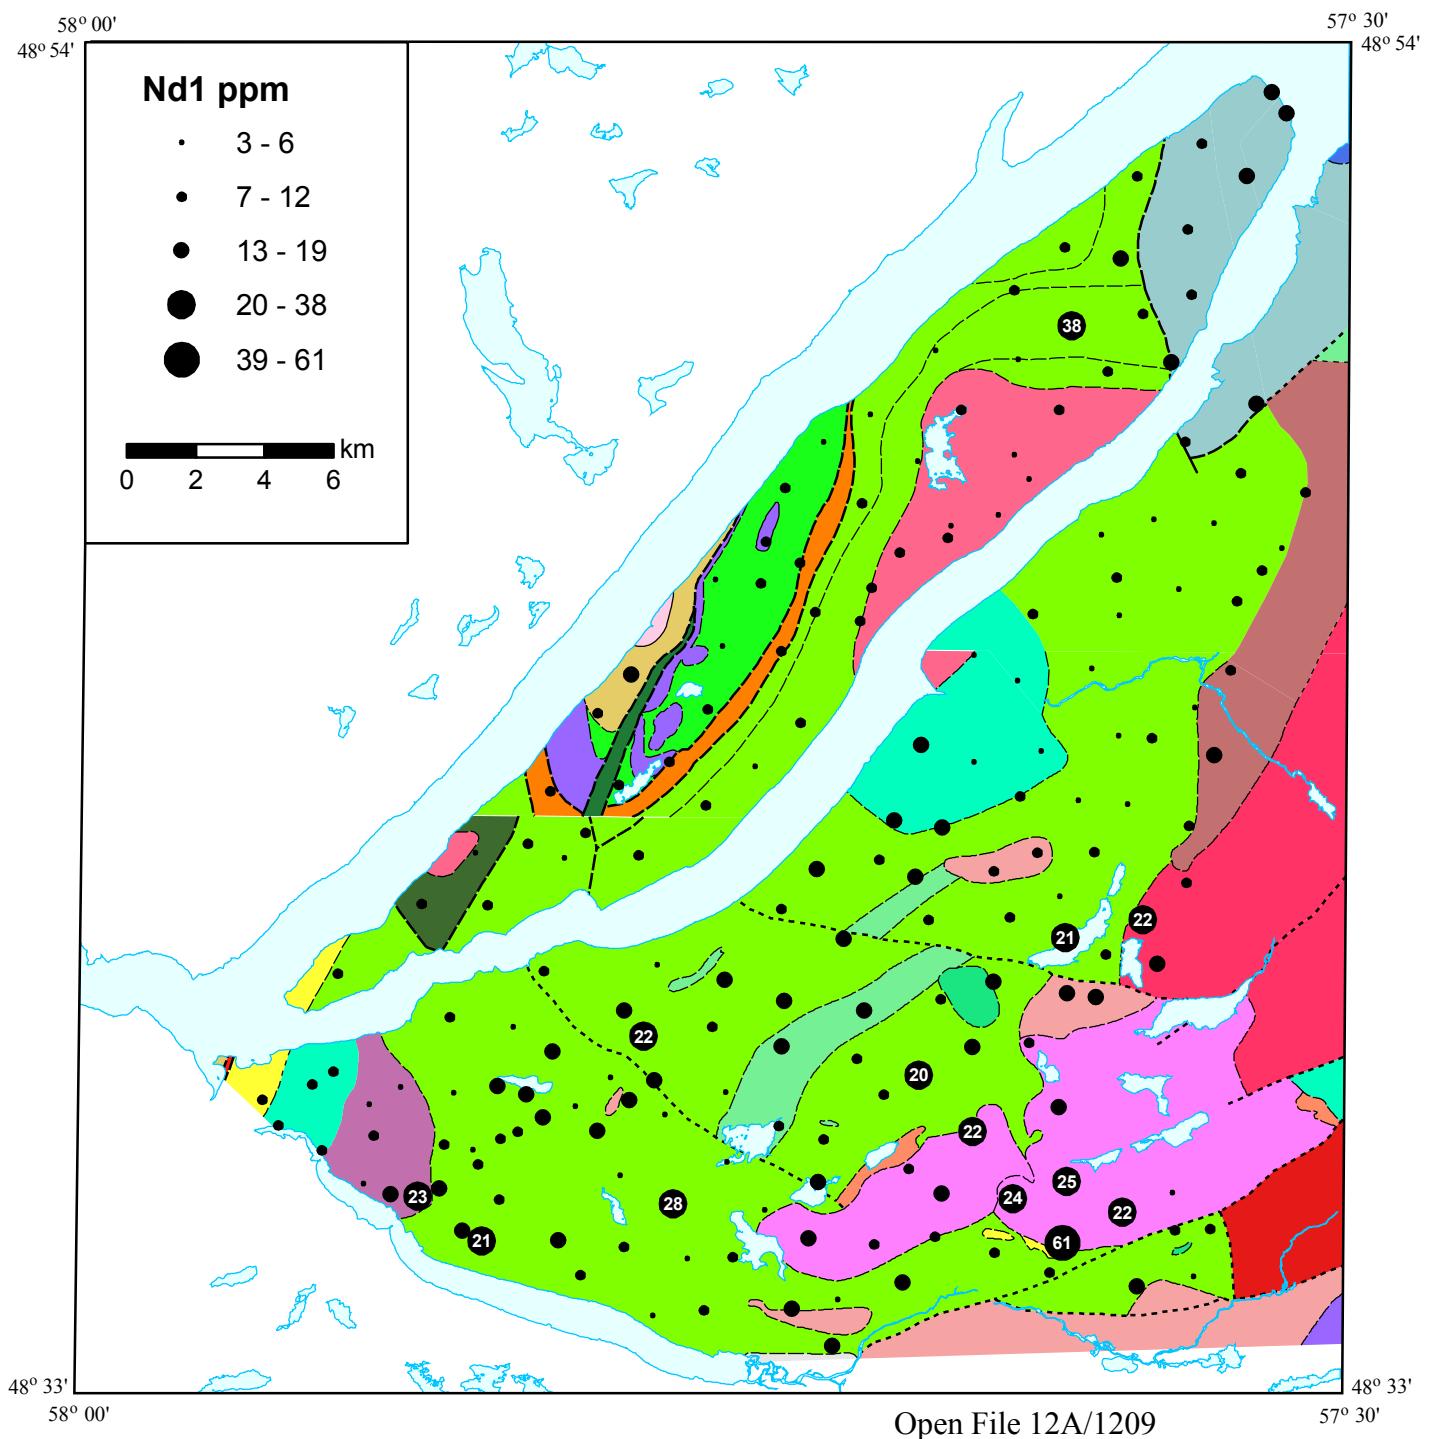

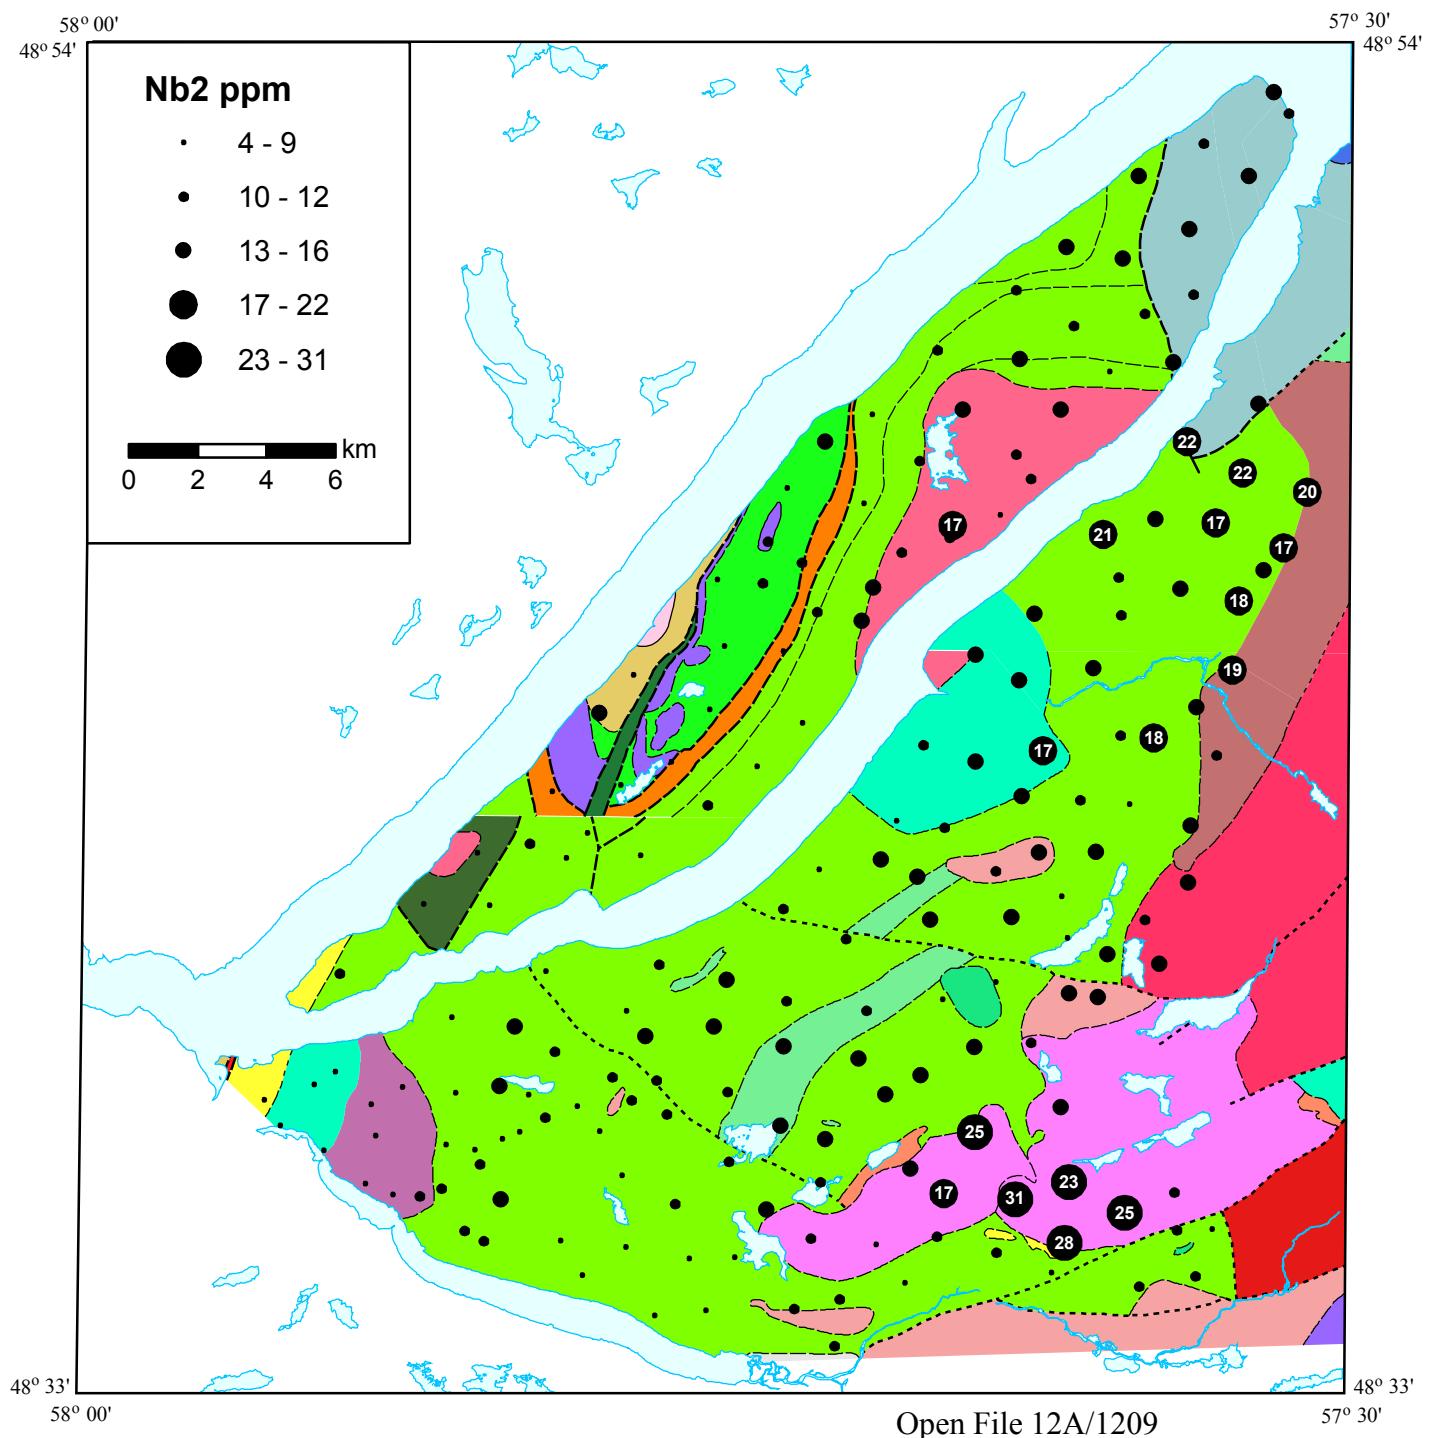

*Distribution of magnesium in till.*

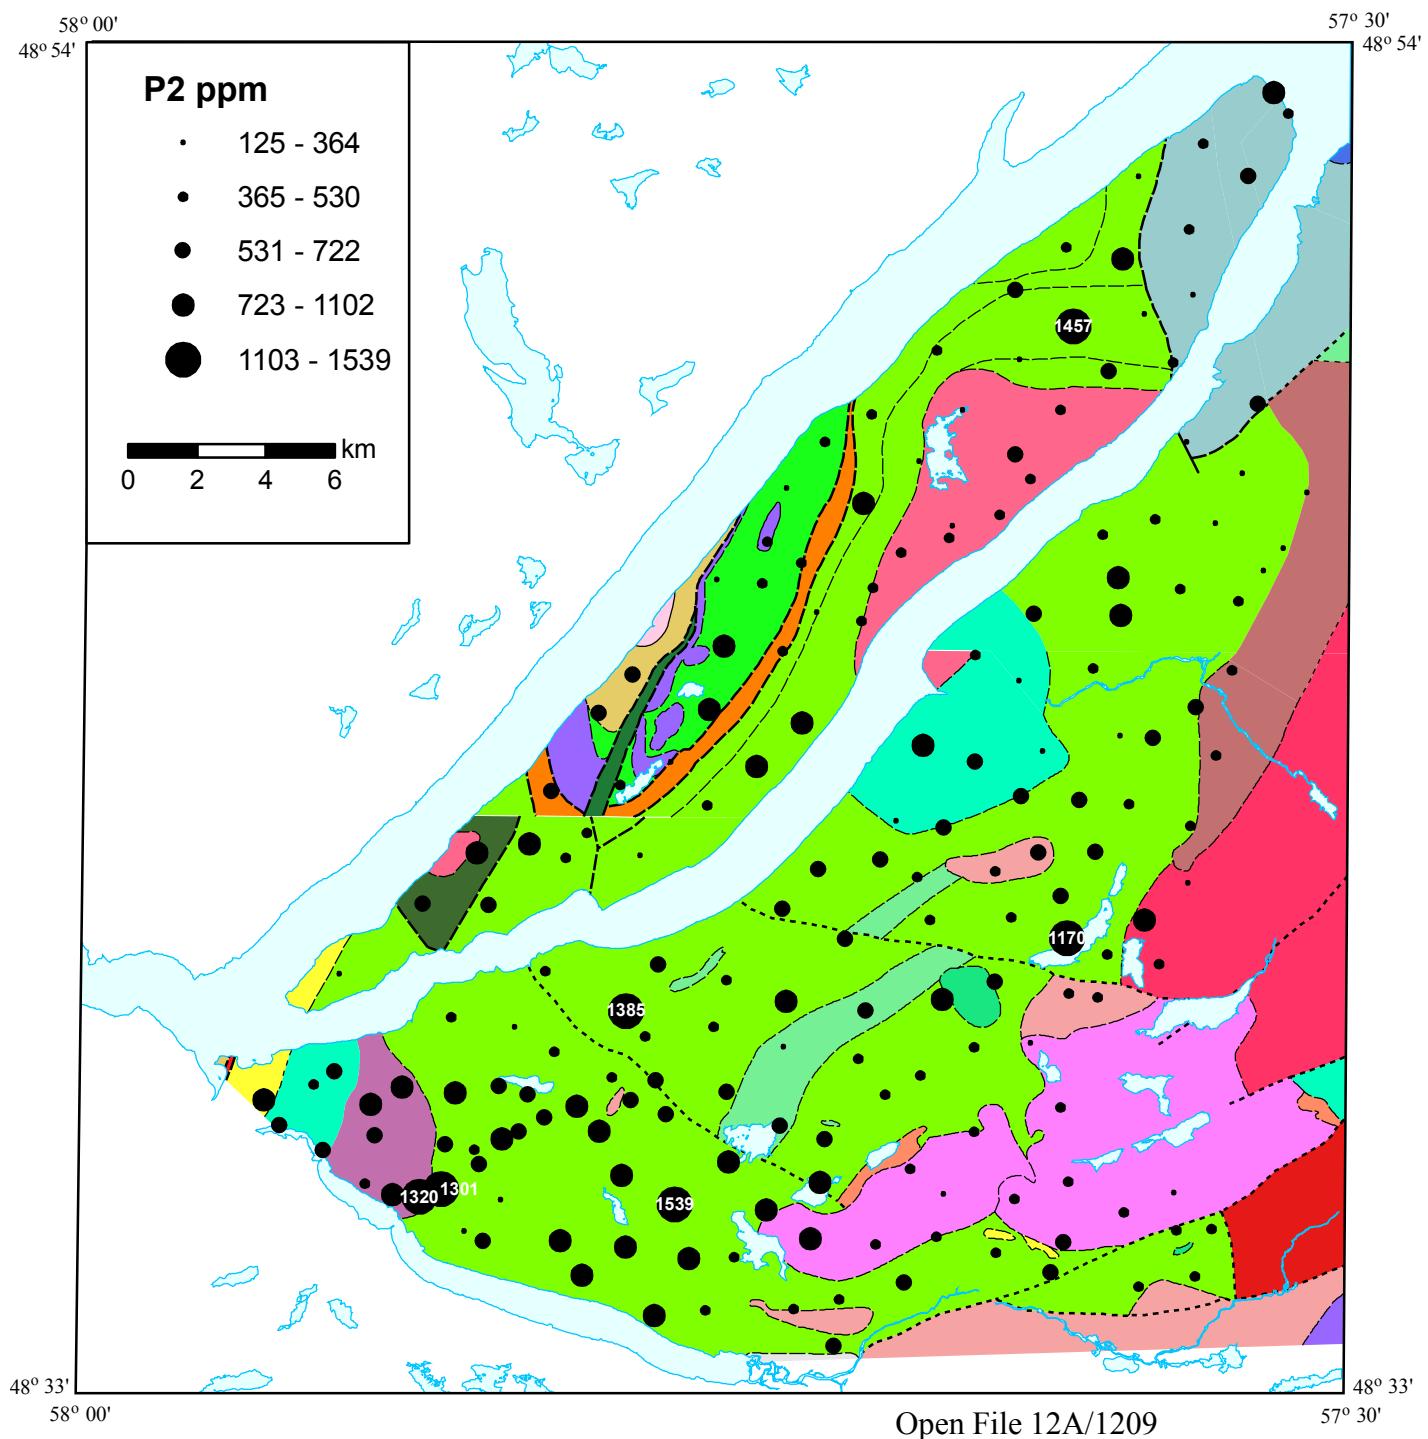

*Distribution of molybdenum in till.*

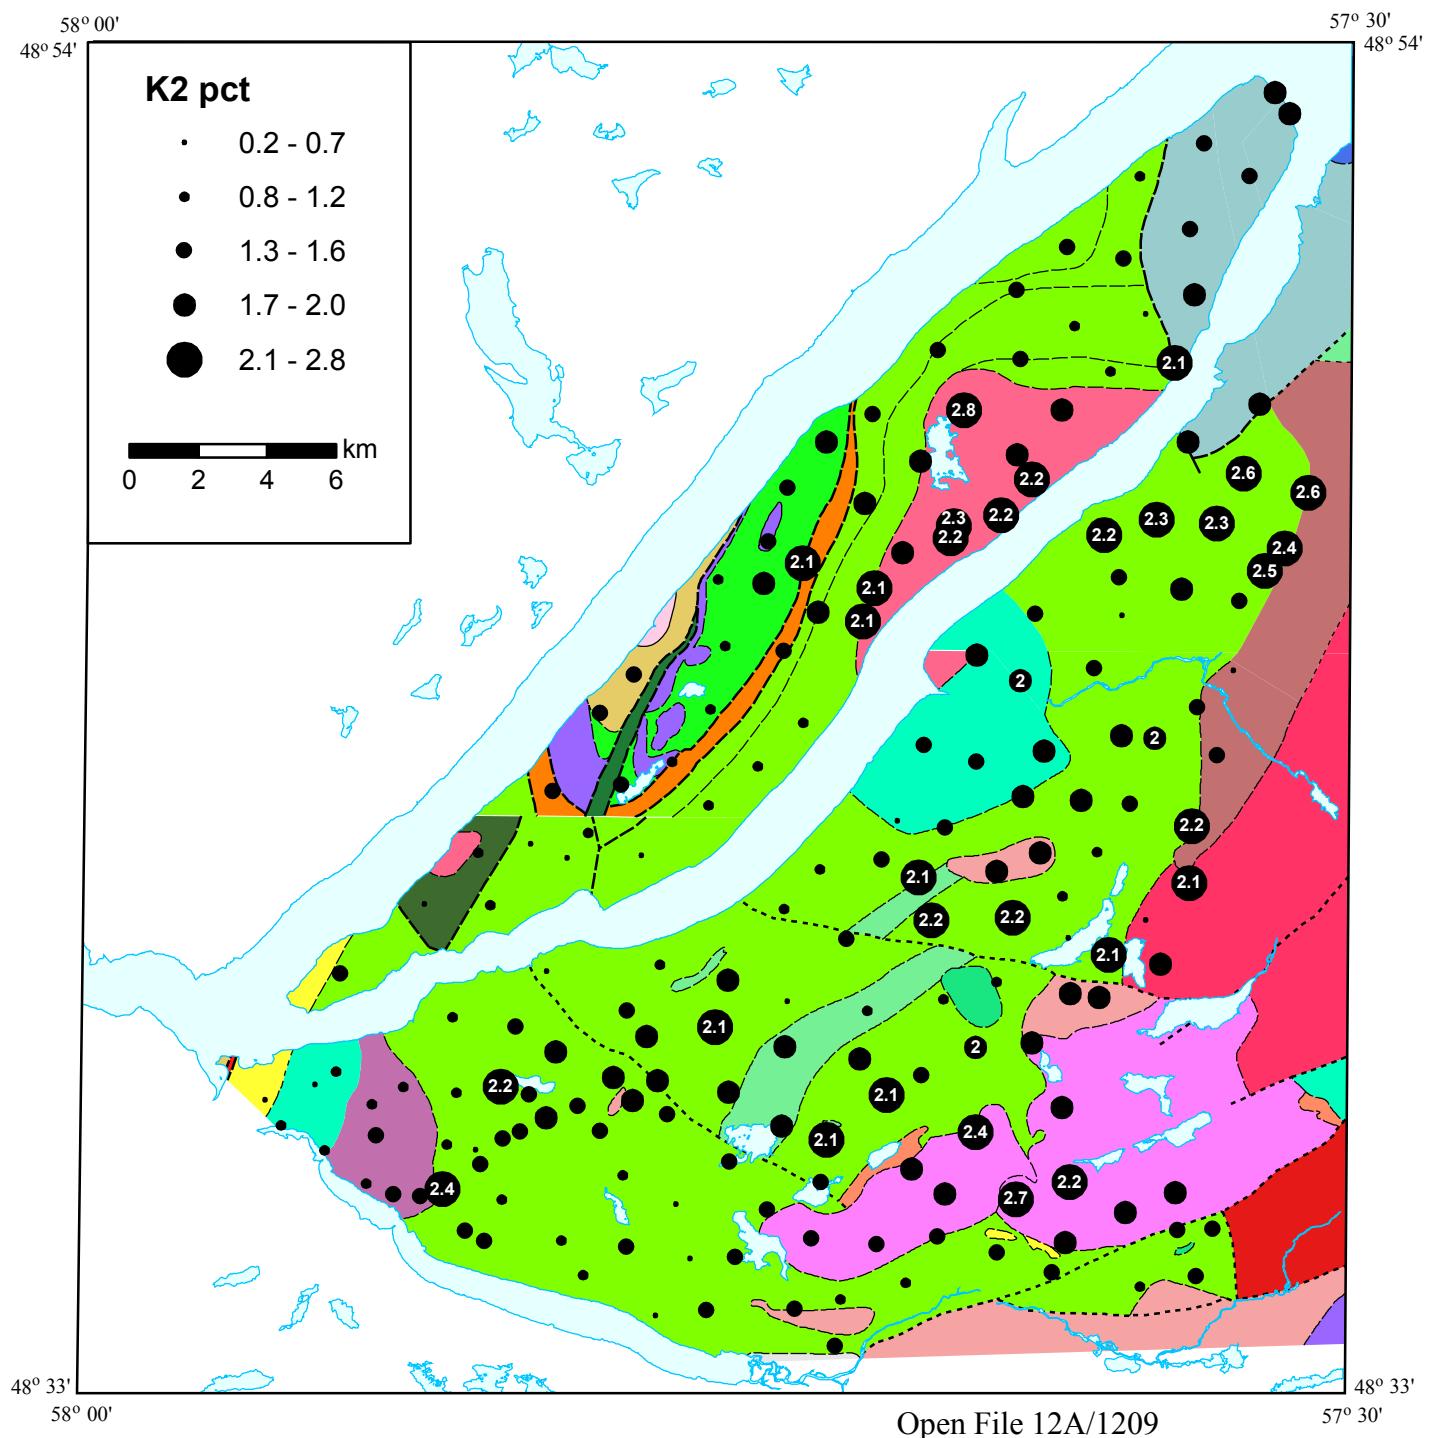

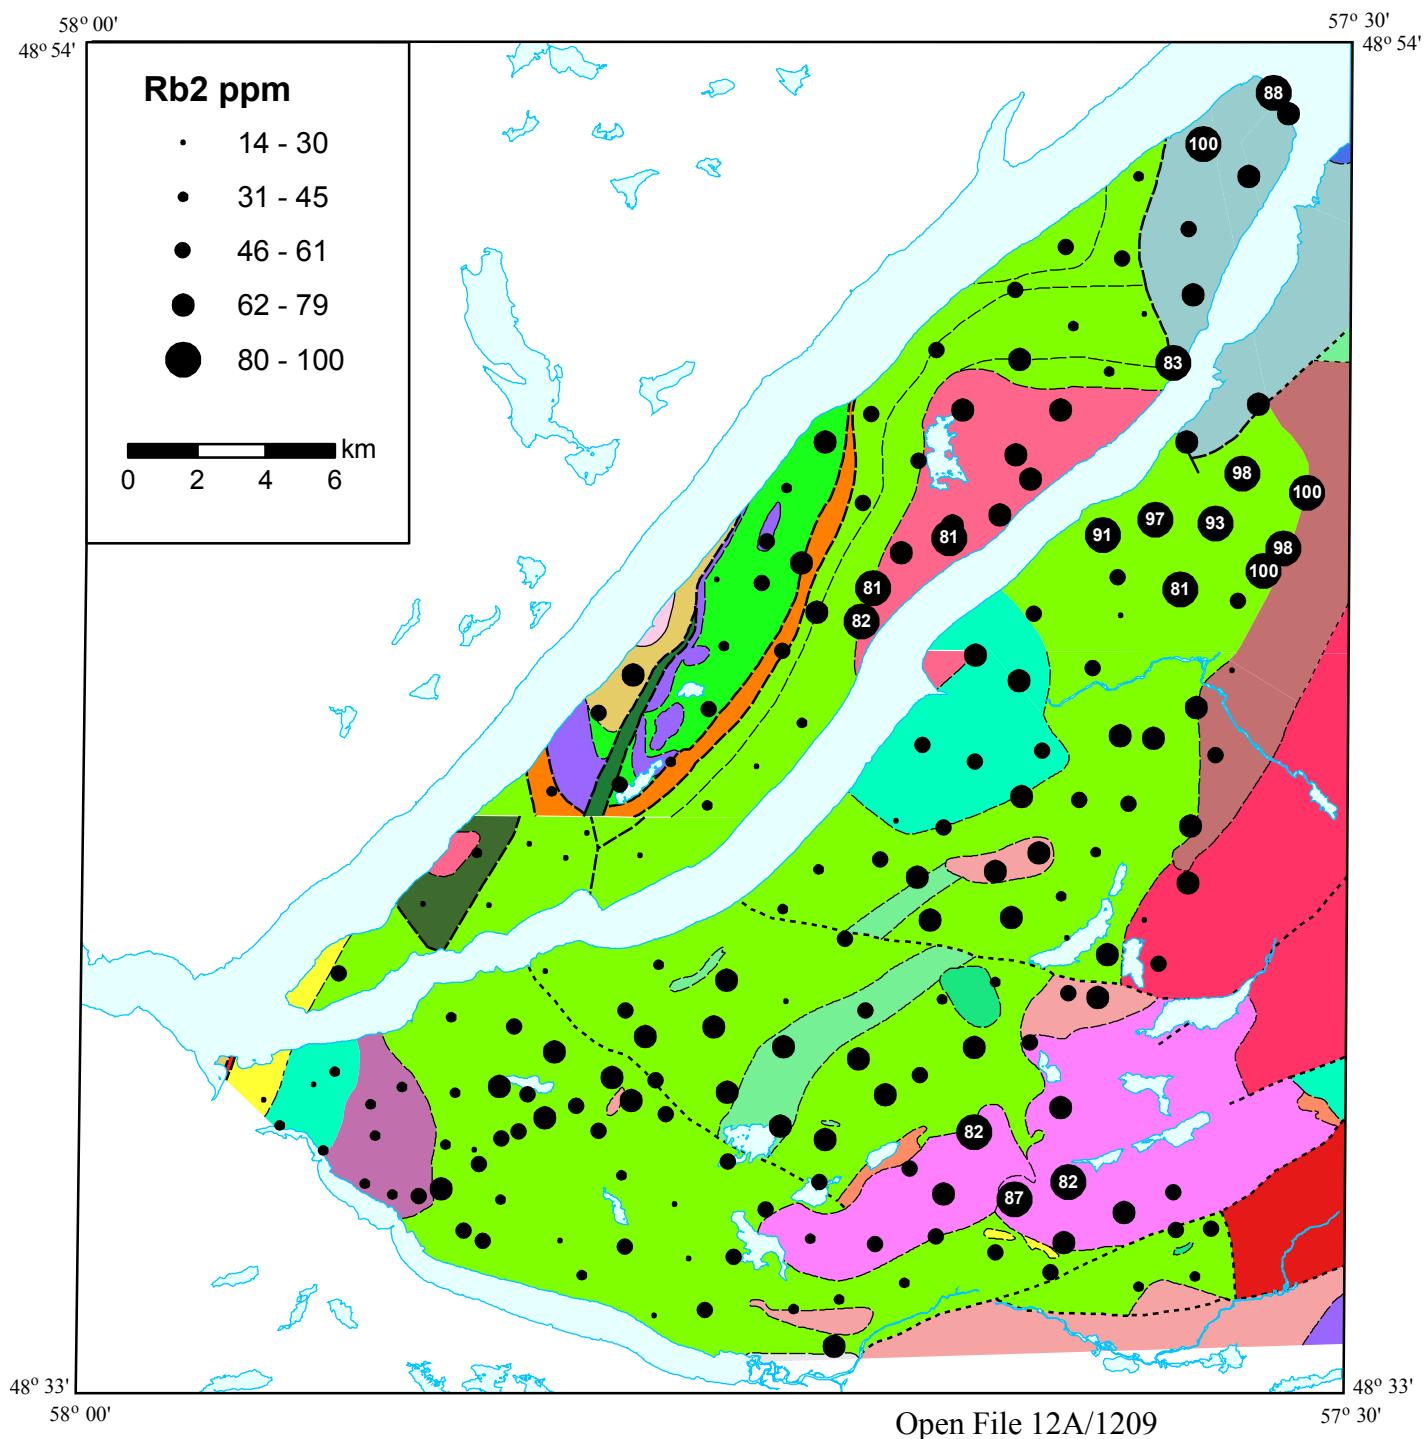

*Distribution of niobium in till.*

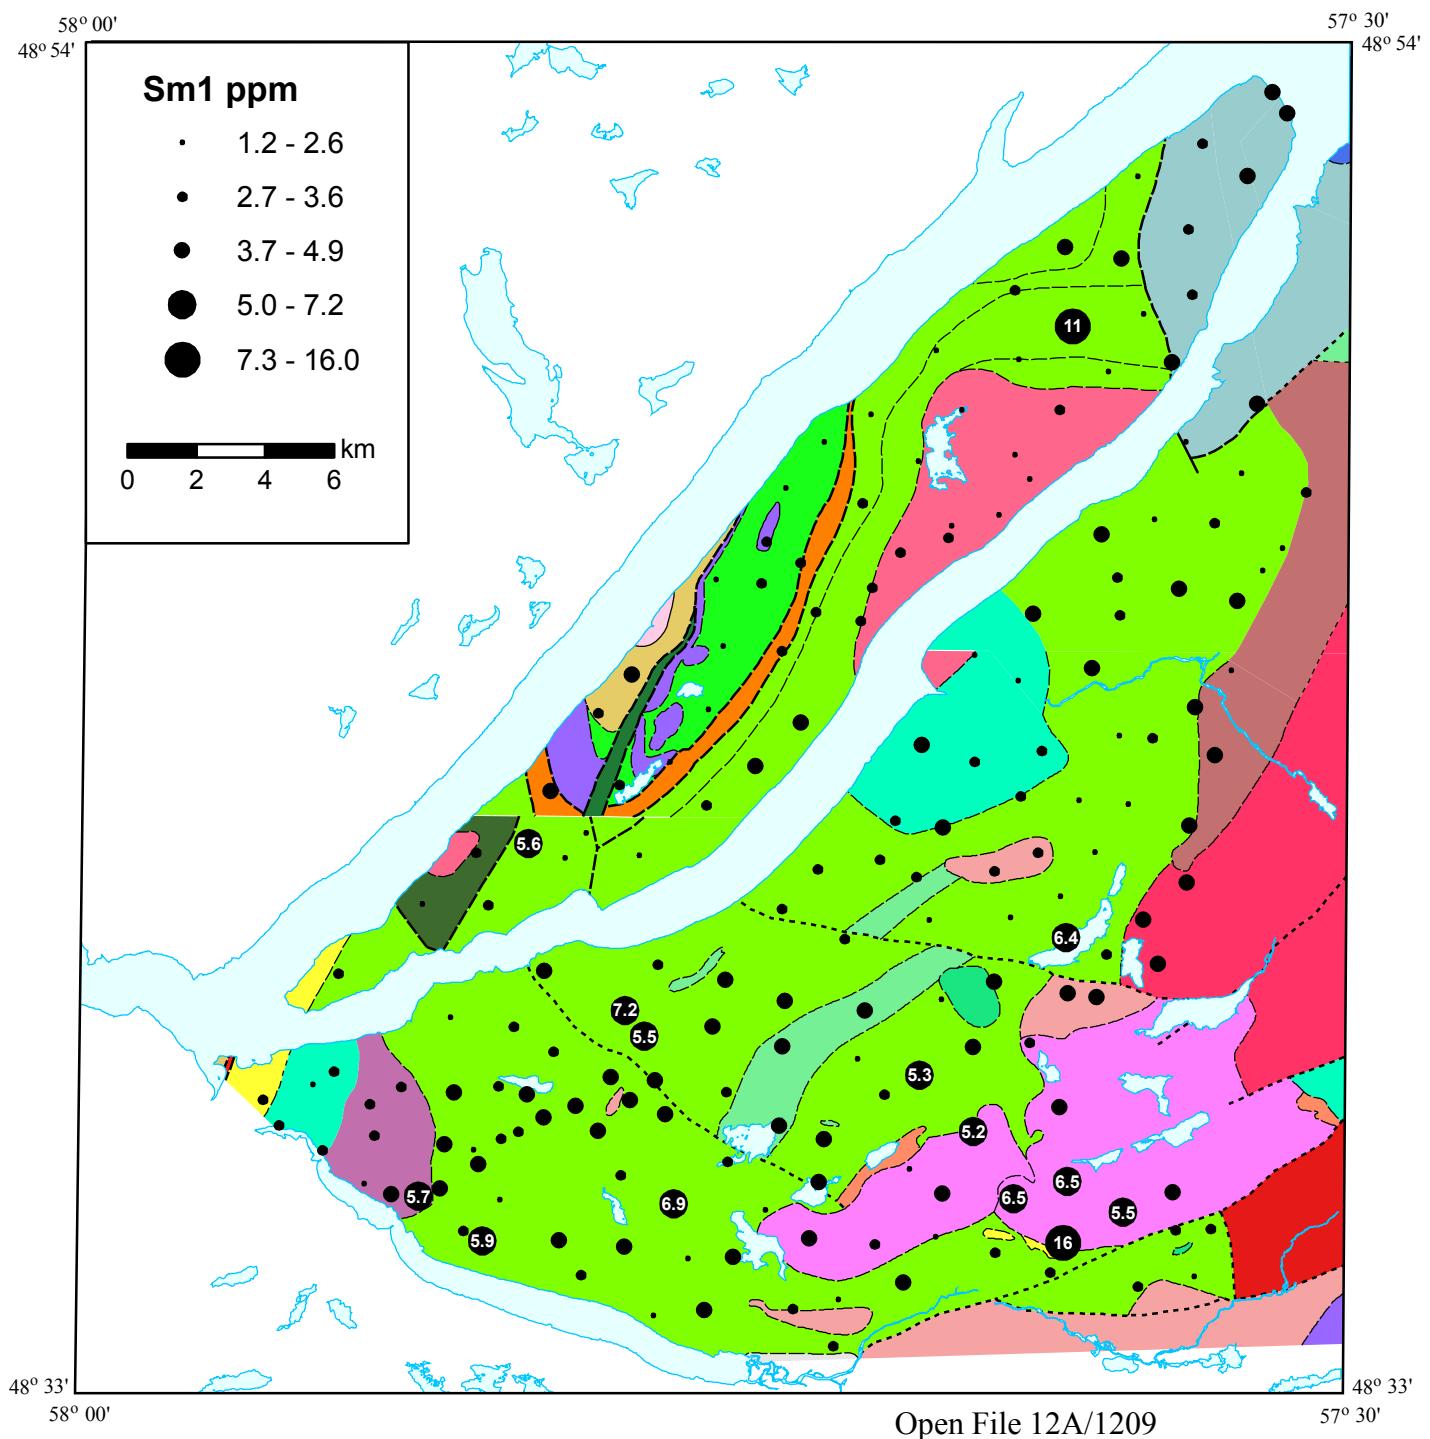

*Distribution of phosphorous in till.*

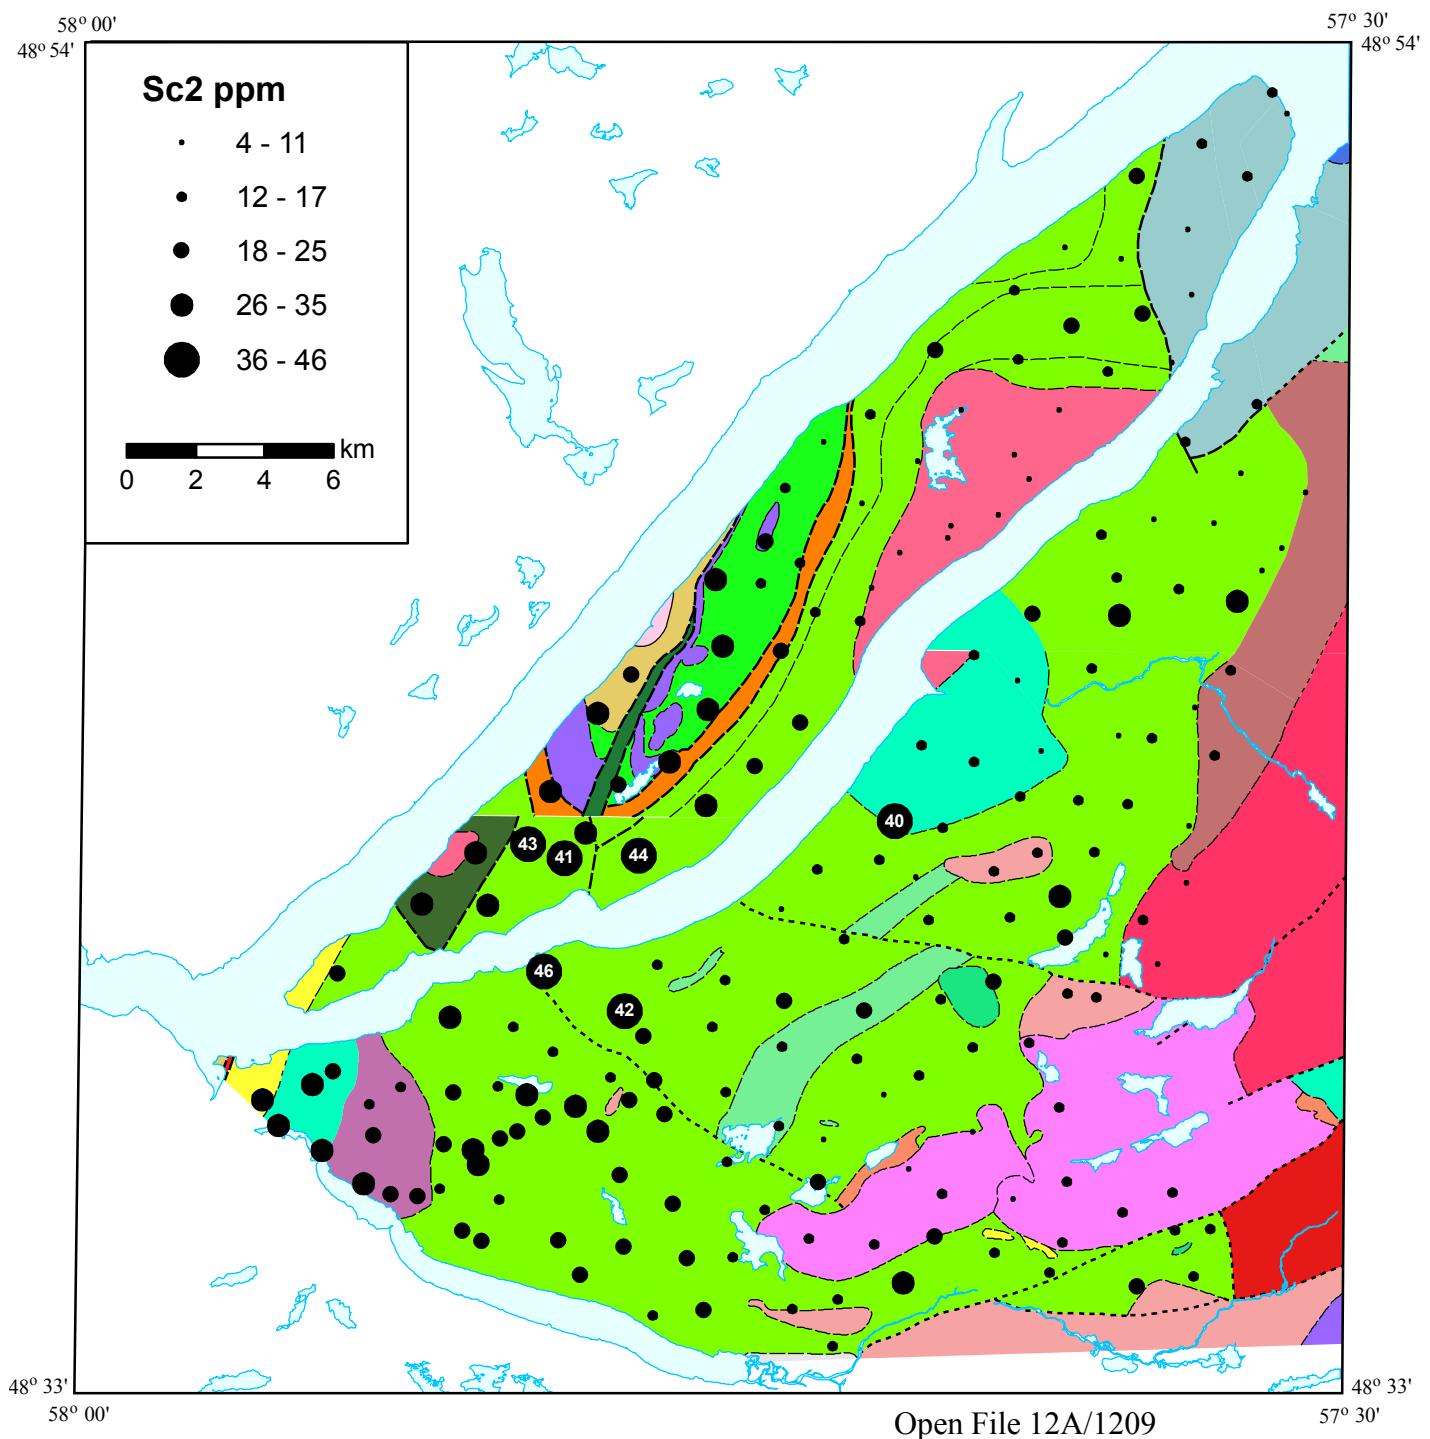

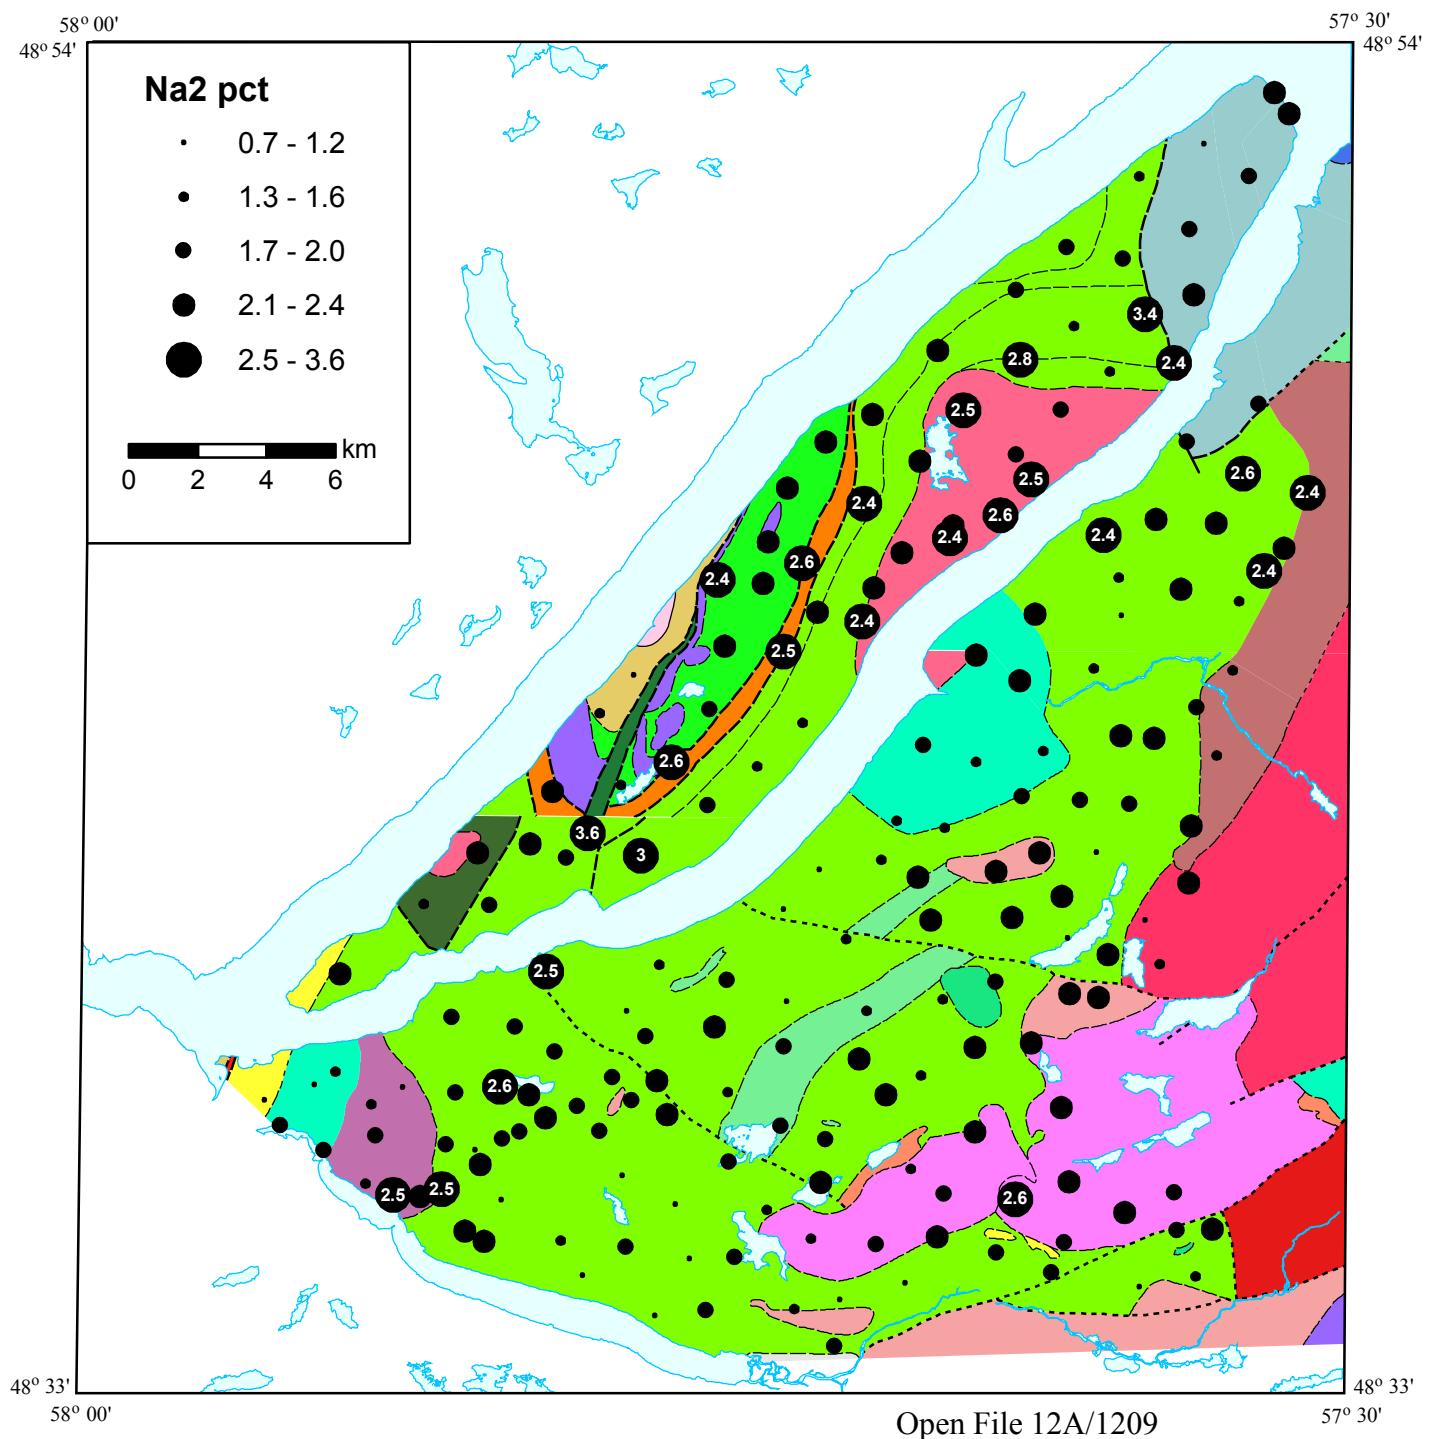

*Distribution of rubidium in till.*

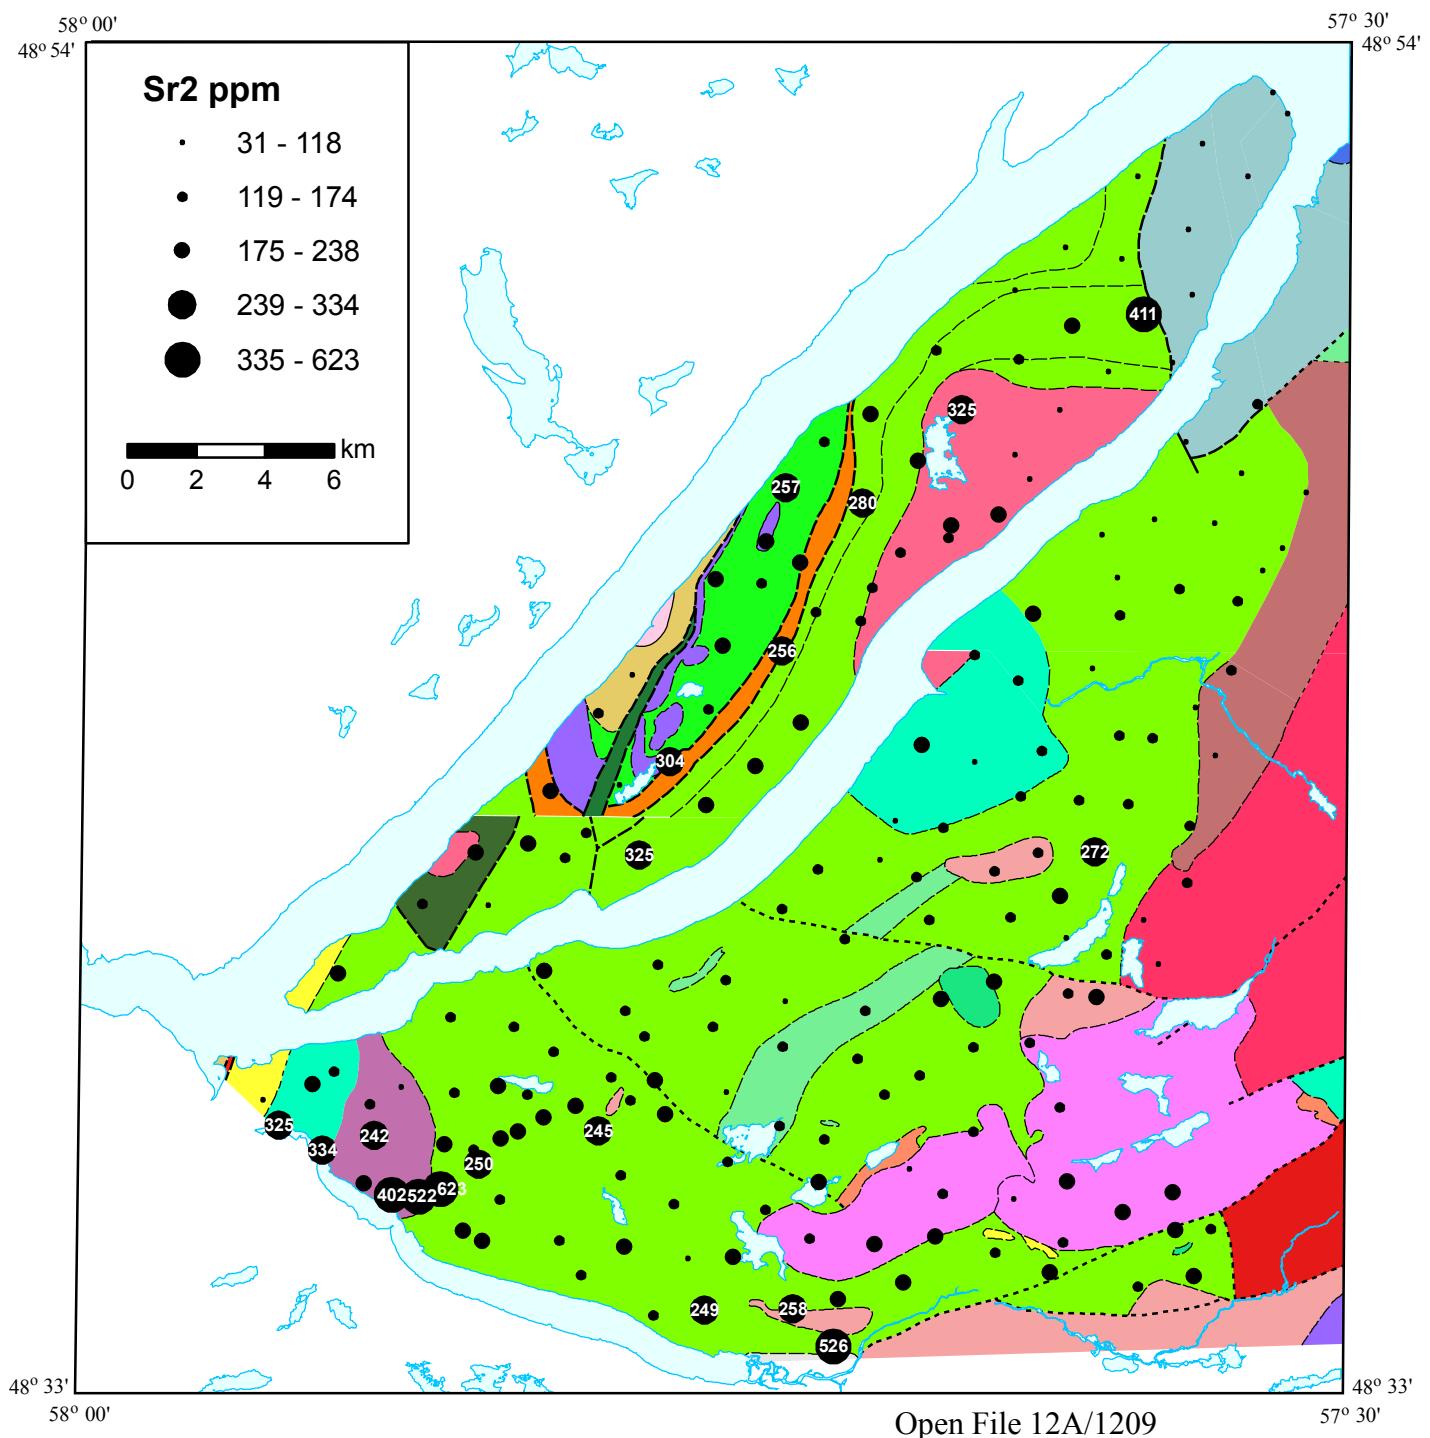

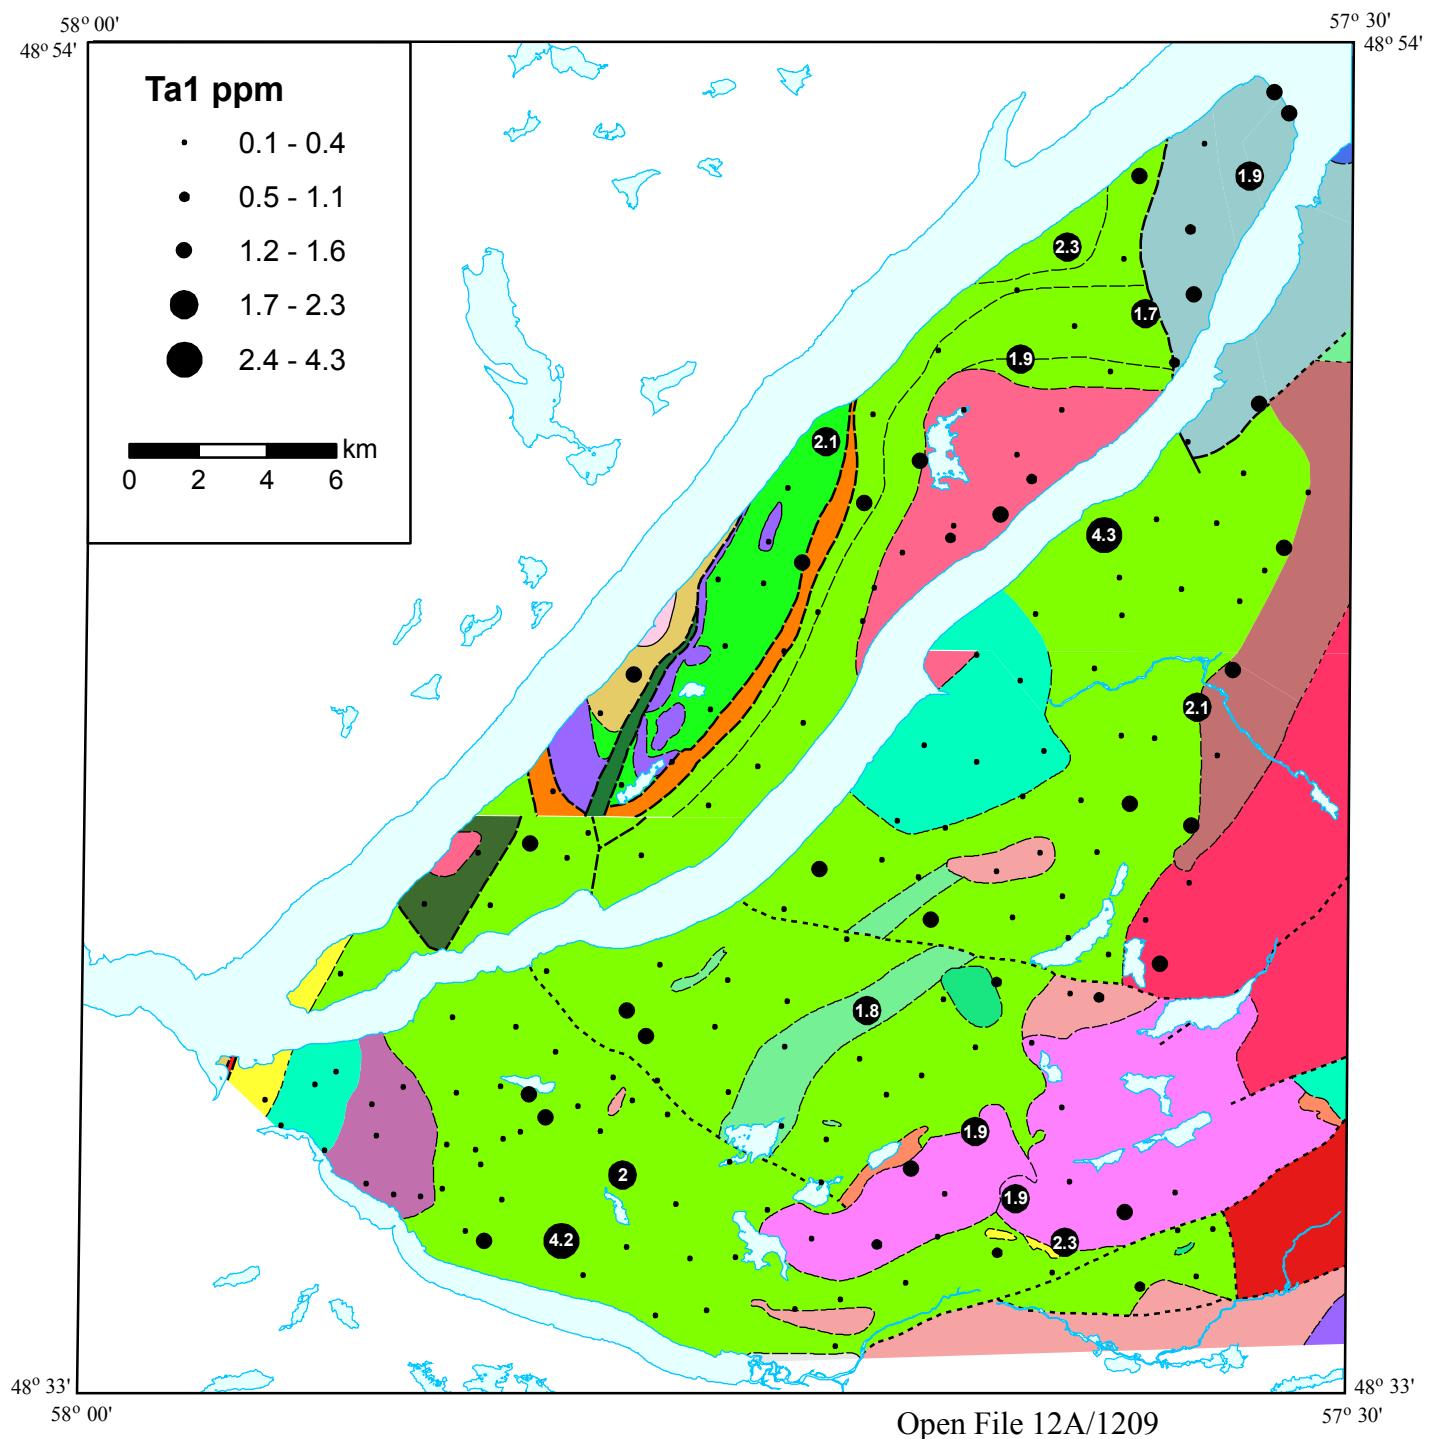

*Distribution of samarium in till.*

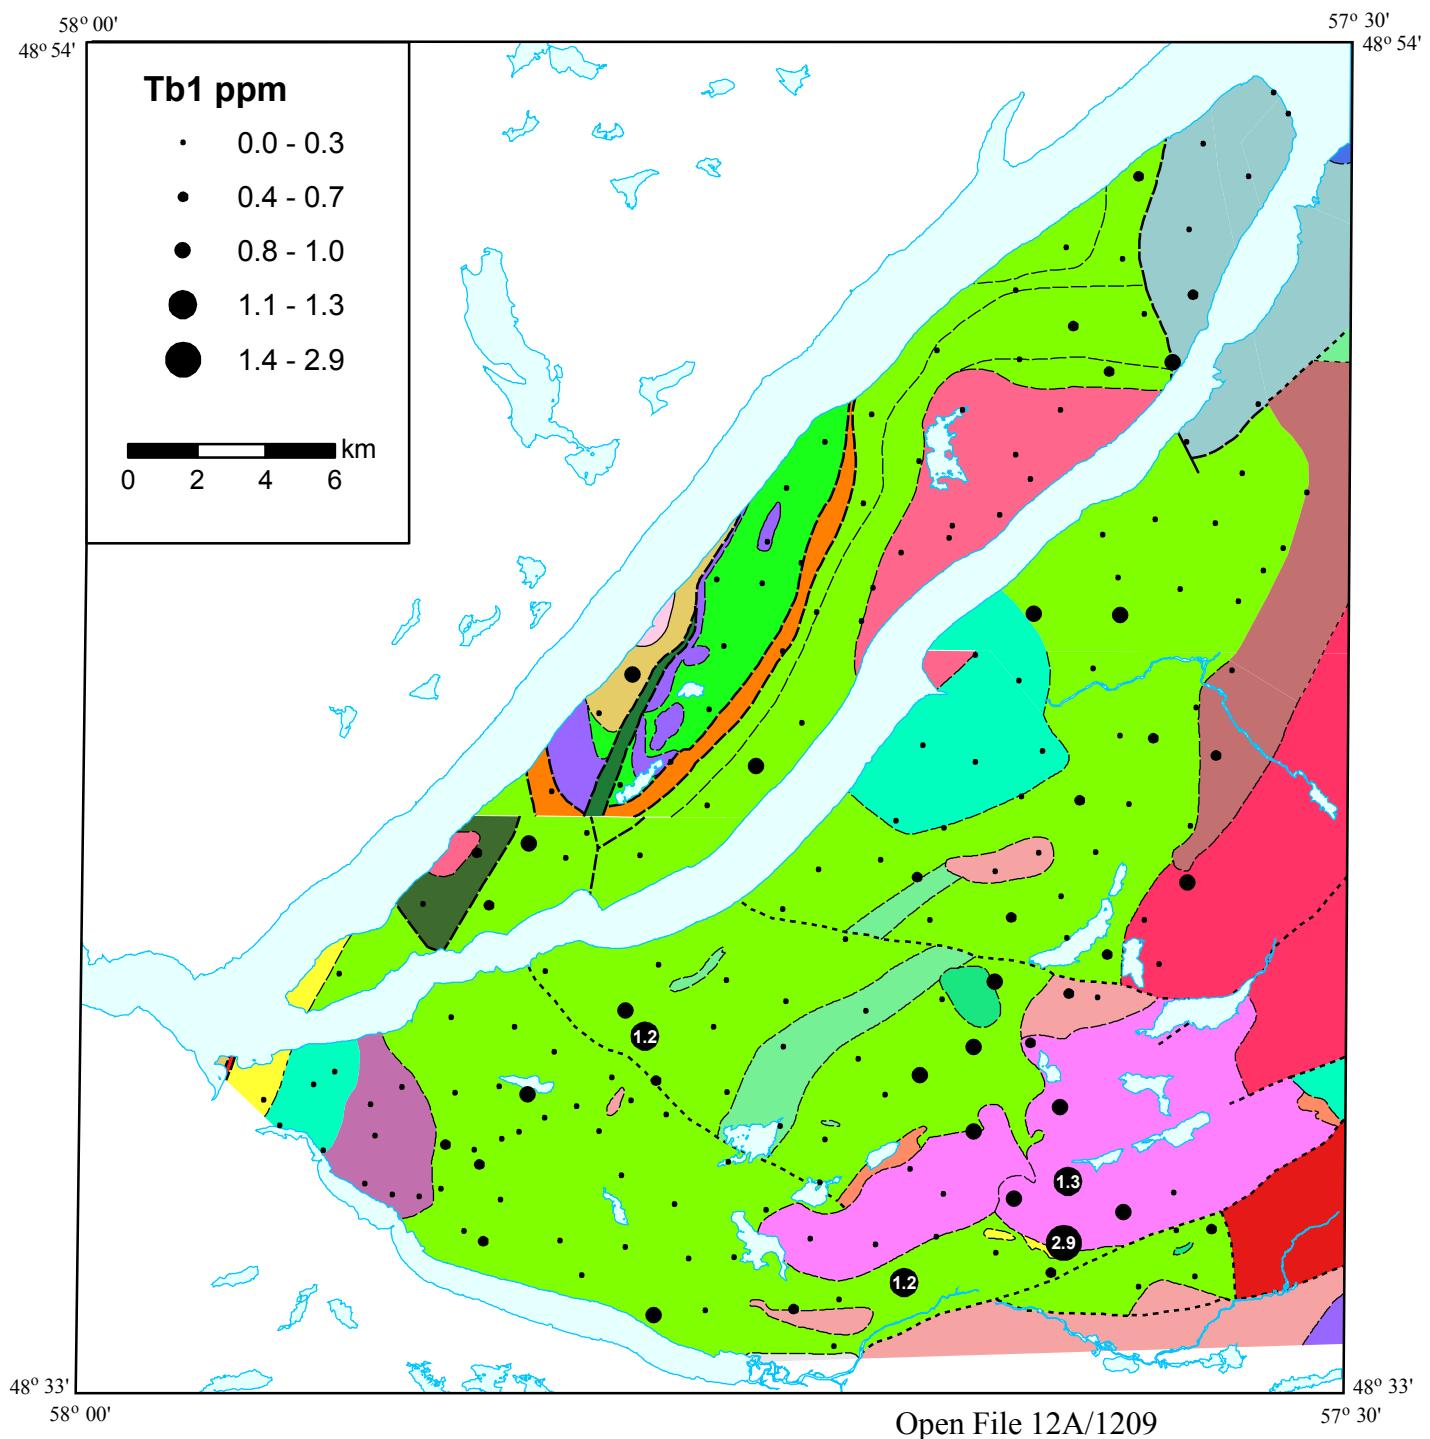

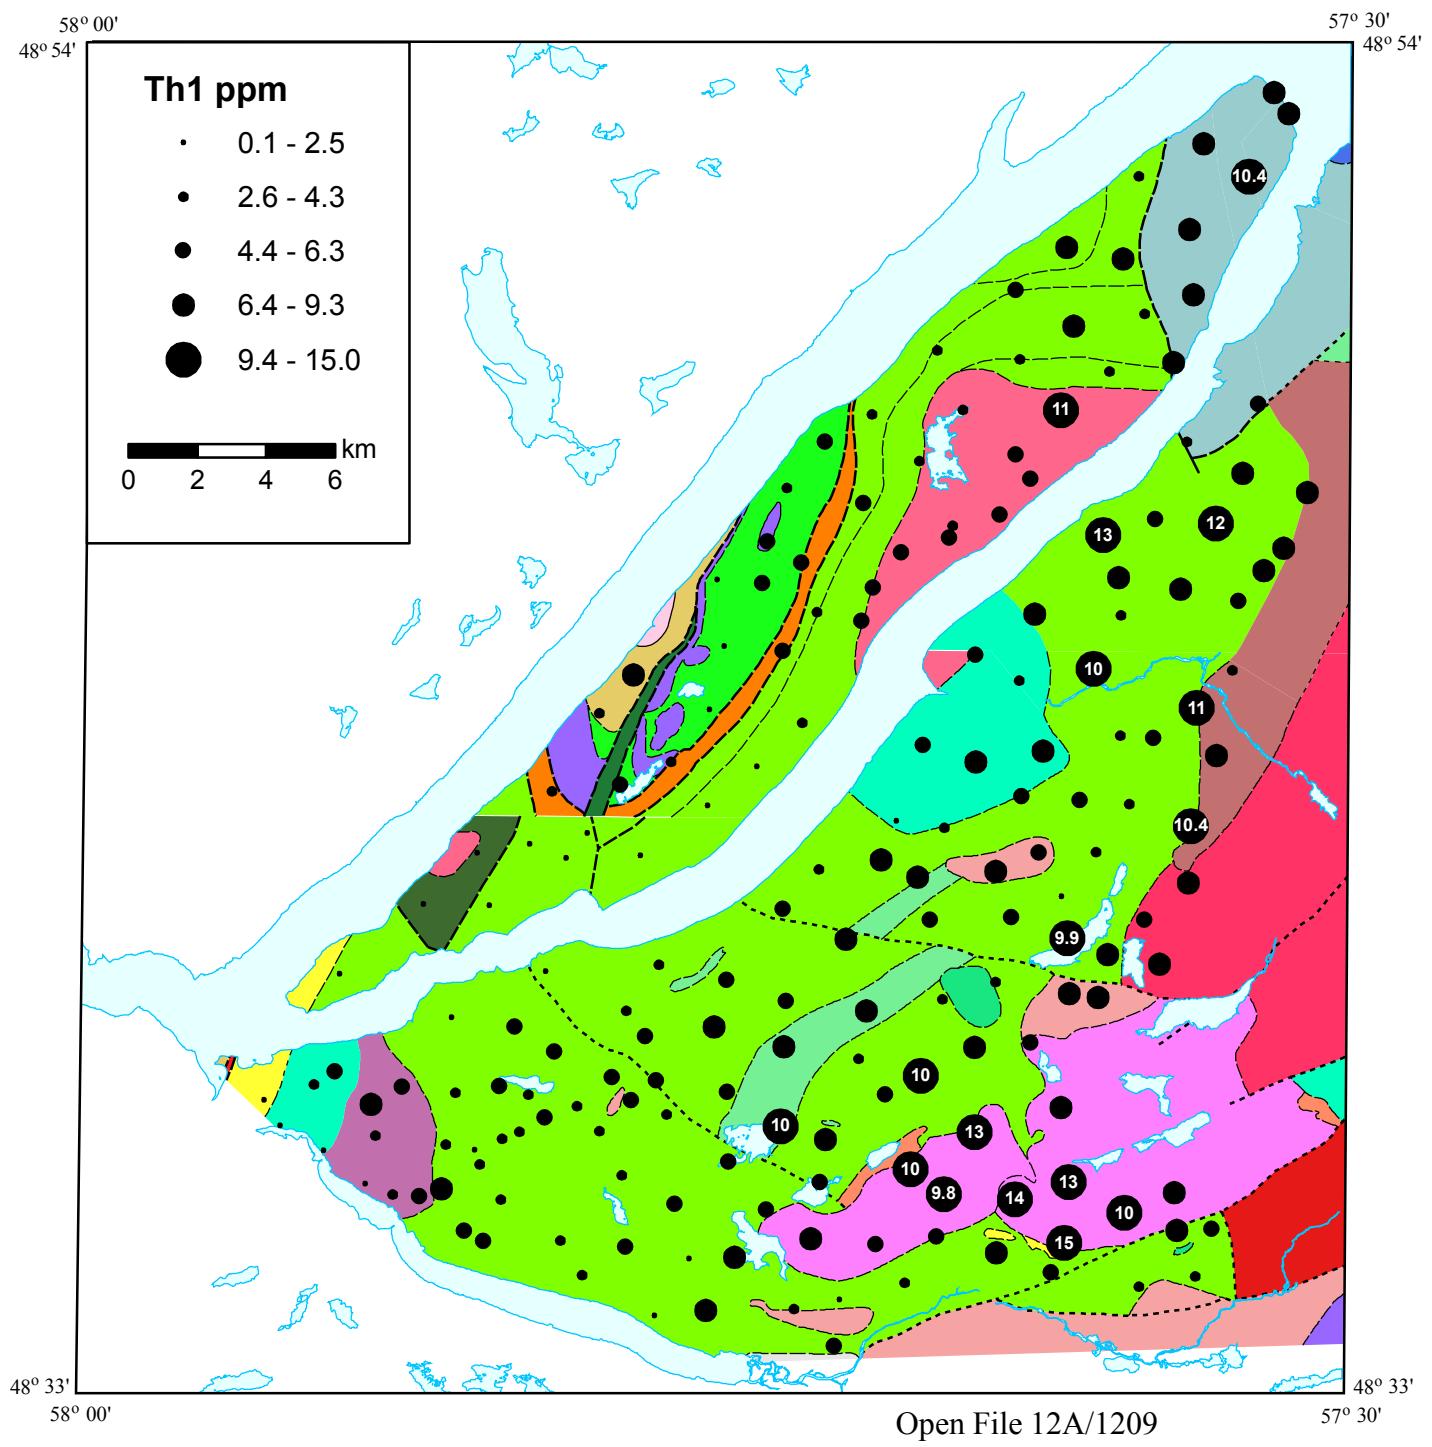

*Distribution of sodium in till.*

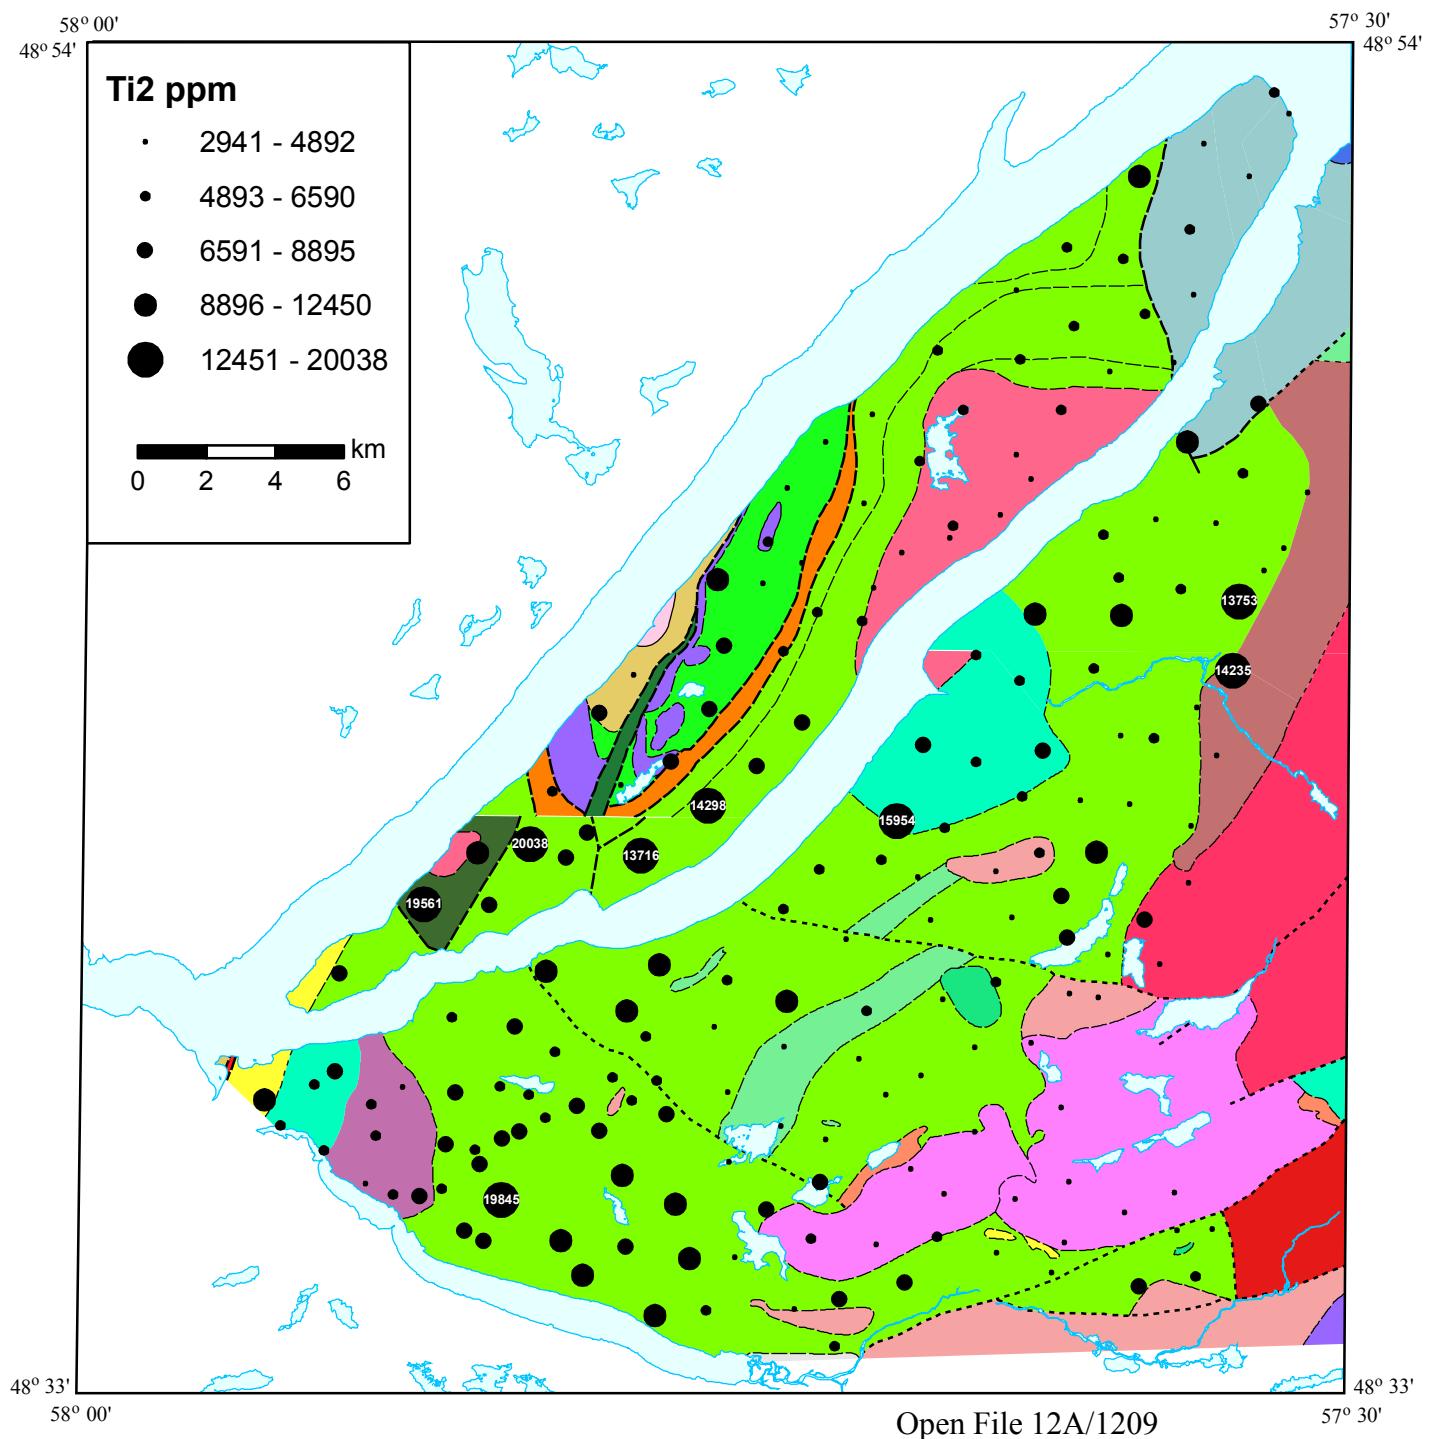

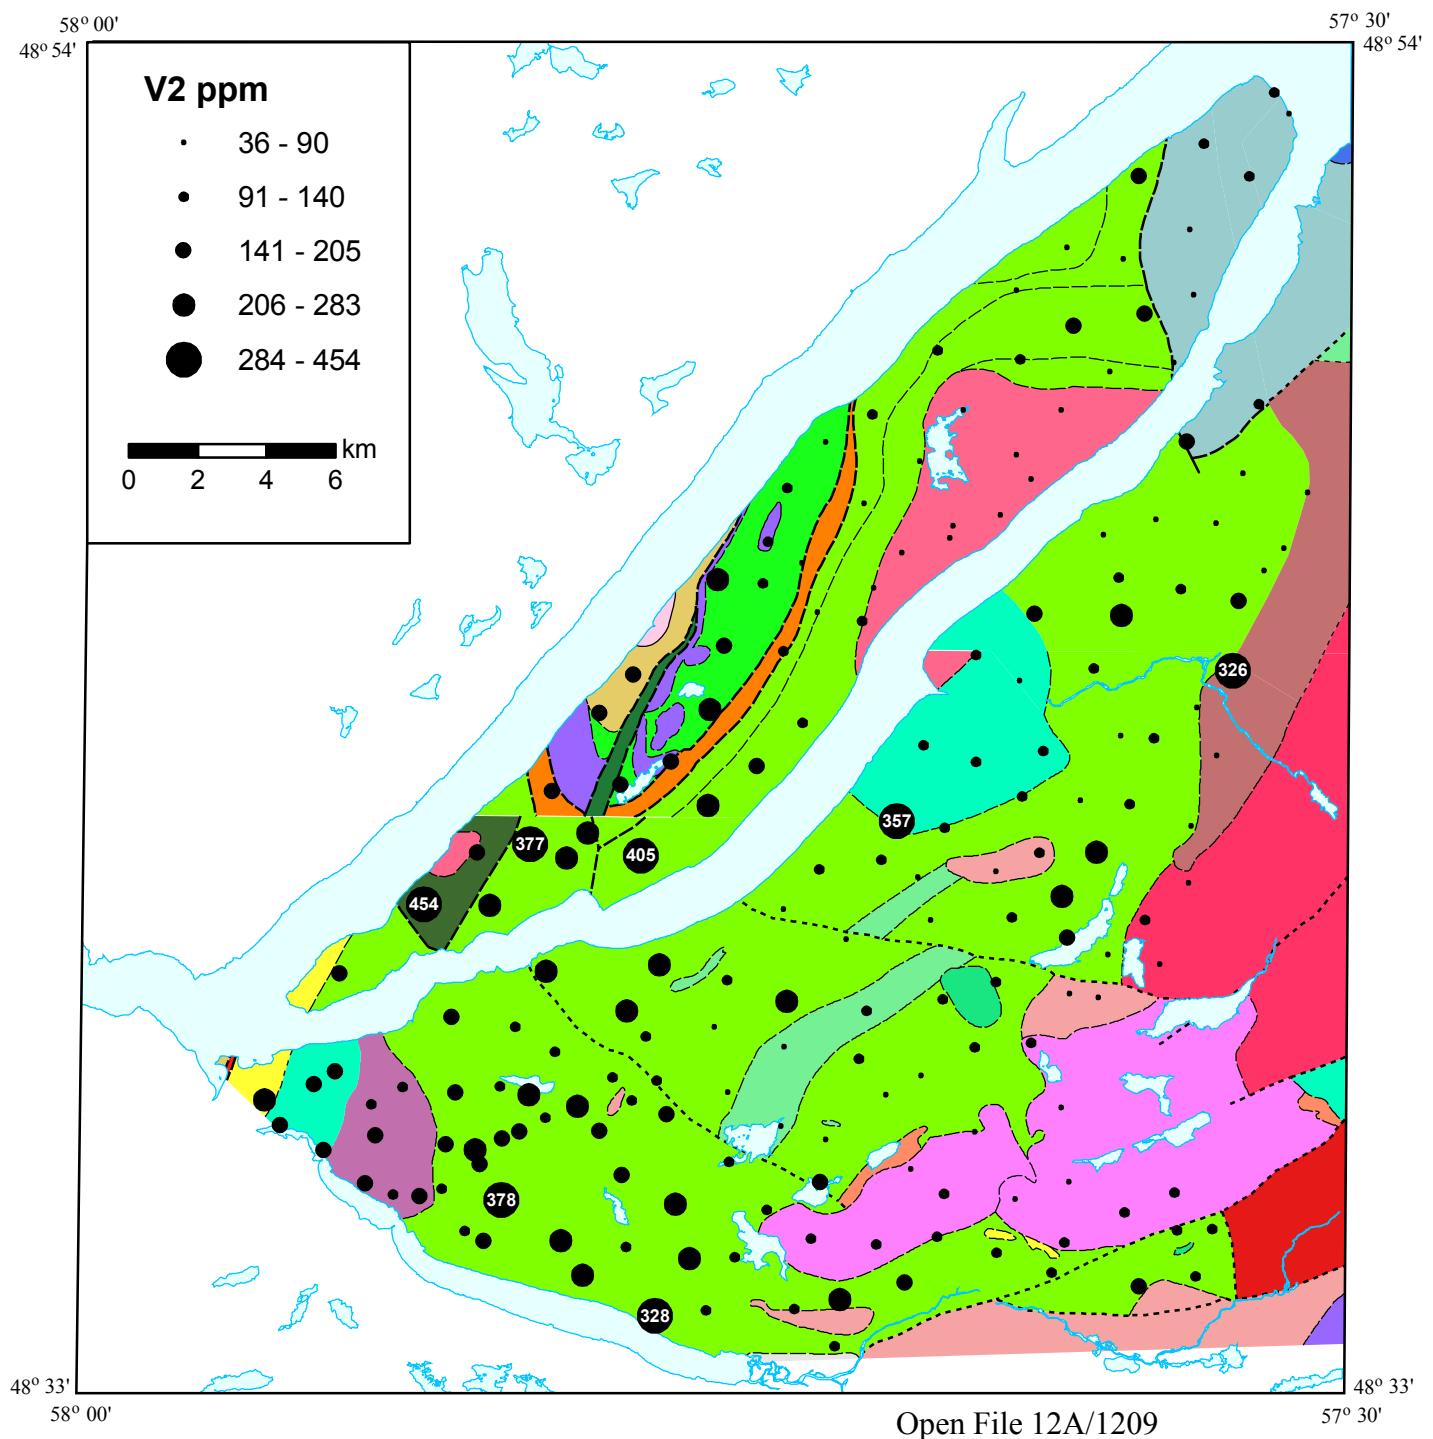

*Distribution of tantalum in till.*

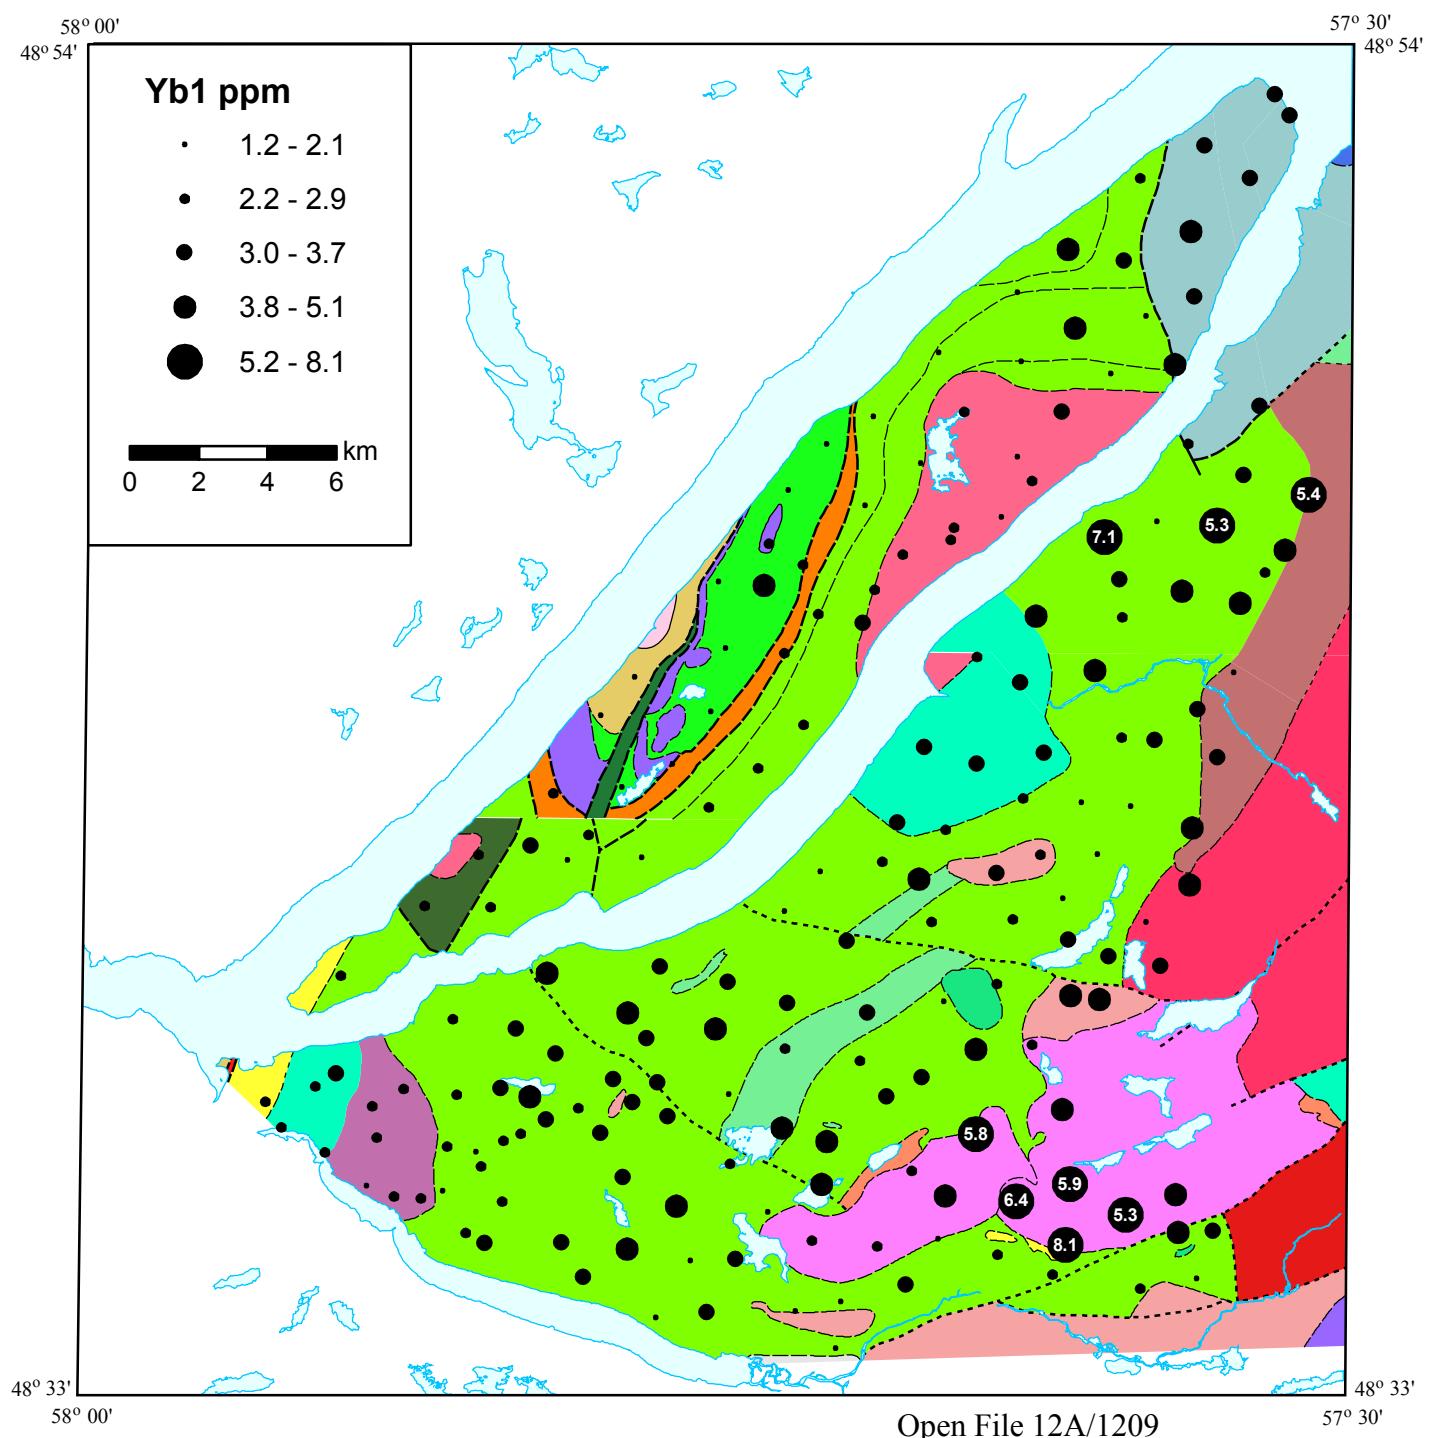

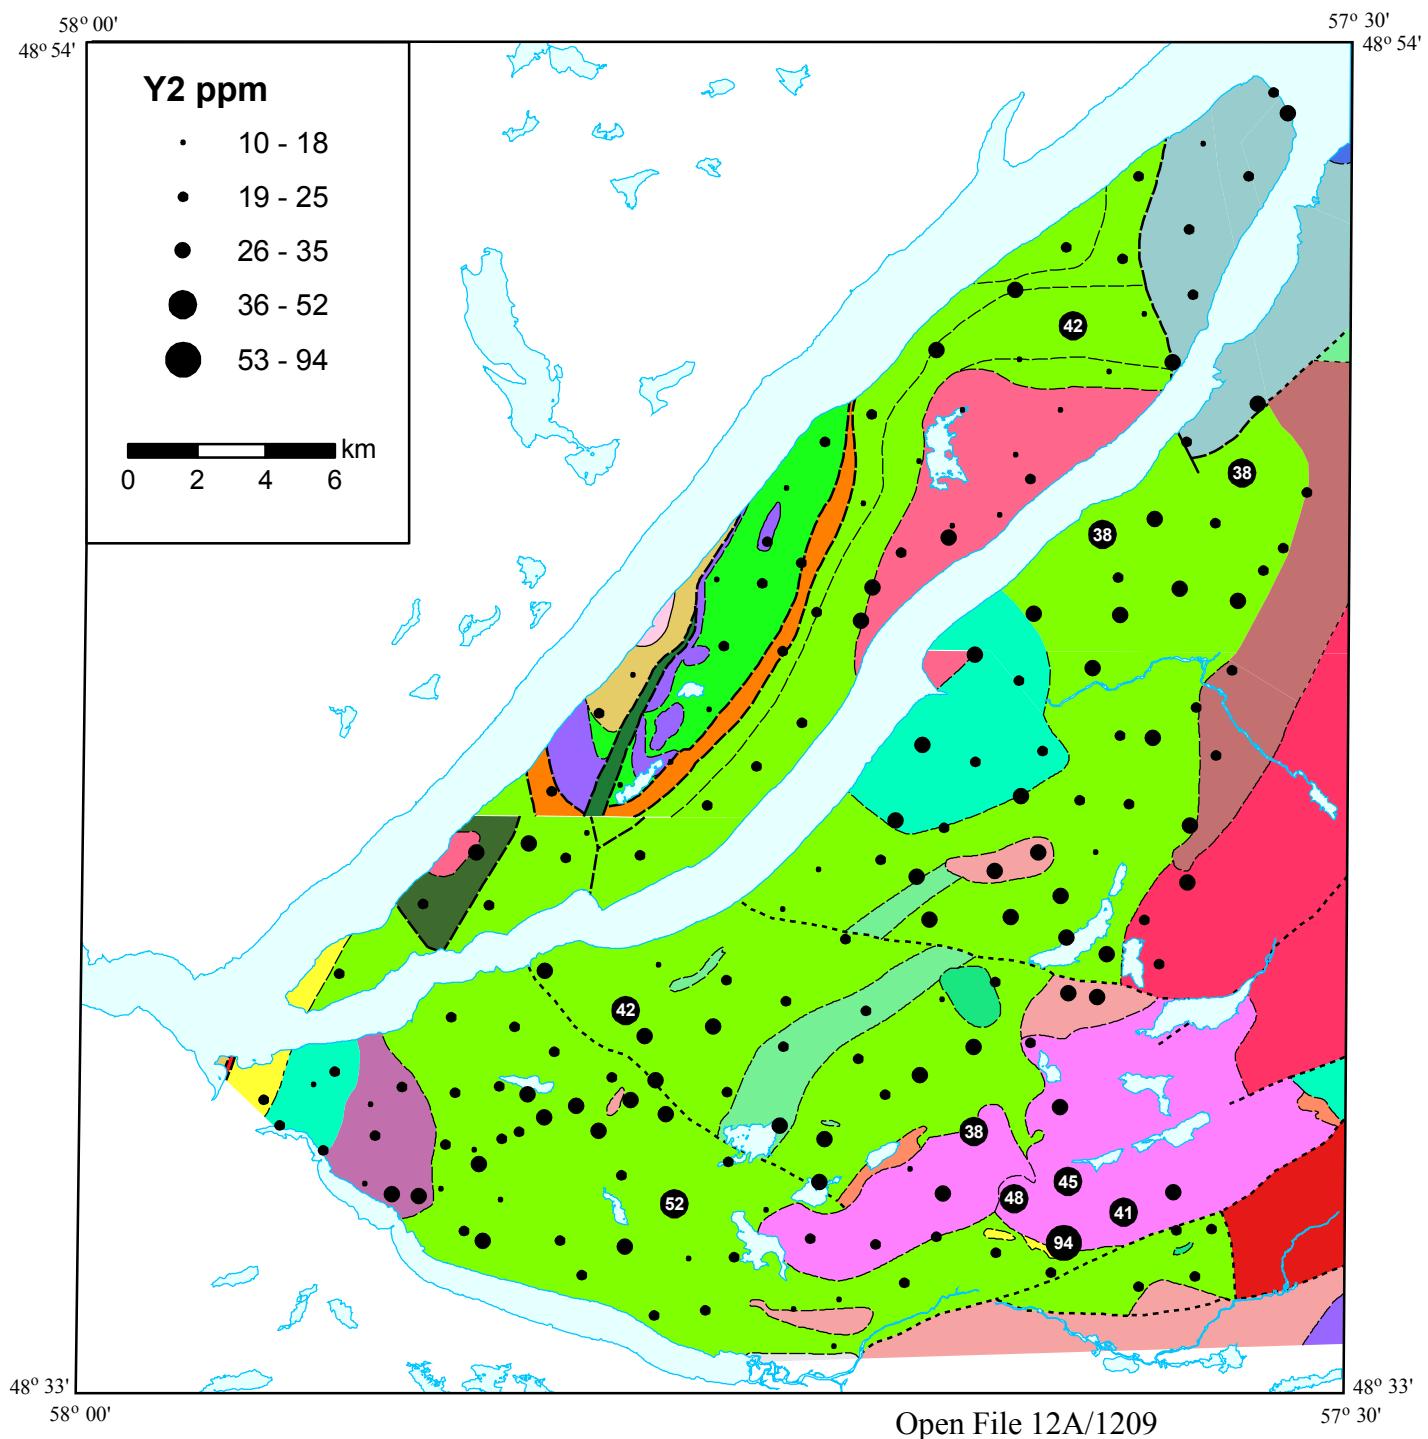

*Distribution of titanium in till.*

*Distribution of ytterbium in till.*

*Distribution of yttrium in till.*
