# Some Applications of Geographically Weighted Regression to Regional Geochemical Data

Stephen Amor January 17, 2019

## **TOPICS TO BE COVERED**

- 1. Ordinary and Geographically Weighted Regression
- 2. Earlier Studies
- 3. Datasets in this study
- 4. Results:

Local R<sup>2</sup>

Residuals

5. Issues still to be addressed

### Ordinary Least Squares (OLS) Regression Explanation of Residuals

## Simple (curvilinear) regression: Volcanic Rocks, NW Ontario

### Example of a quadratic regression equation

### Multiple regression Fitting a surface to bivariate data

**Censoring / truncation of data – an important consideration** 

Analyses below the detection limit can be assigned a value of half the detection limit if there are not too many of them. How if more than 10% of the analyses of an element are below the detection limit, that element is not suitable for regression analysis and should be omitted.

All input variables should be approximately normally distributed and log-transformation of geochemical variables .is often necessary

## **Geographically Weighted Regression (GWR)**

A new equation for each point (only suitable for large, areally extensive geochemical data sets)

The "search radius" within which samples are selected for each regression can be varied

It's claimed that GWR enabled the identification of an anomaly in lake sediments associated with Voisey's Bay, although the input parameters are not known ...

... other methods, such as "filtering" the data, can also enhance the lake-sediment signal at Voisey's Bay; however they also identify other strong anomalies that are apparently (despite extensive exploration) not associated with mineralization. Toolbox

## How it's done

GWR is an option within the "Modeling Spatial Relationships" module of the ArcGIS toolbox.

B and Antime     Call Jointhel, 2008     Call Jointhel, 2008		Input Instance The future class containing the expension of integration services
9 Total Nation Intel Second State Factor Backwarth redfood Acci	a	

"Input features" refers to the data from which the regressions will be calculated

The "dependent variable" is the variable to be predicted (on the left in the regression equation)

The "explanatory variables" are used to predict values of the dependent variable. Also referred to as "independent" or "predictor variables"

The "output feature class" holds the results of the GWR. The default is to add it to the ArcGIS GDB database.

#### Output

## **GWS Output**

Dependent variable predicted from regression equation(log-transformed)

## **Earlier (pre-GWR) studies**

Areal distributions of the co-associated elements look very similar, at least at regional scale.

1: Clastic, fine-grained 2: Clastic, coarse-grained 3: Organic ooze 4: Organic, granular 5: Organic, peaty

### Elements in the association tend to be enriched in samples rich in inorganics

equations \_\_\_\_

Modelling of clastic component enabled extraction of non-clastic residual component. High Ba residuals coincide with barite in esker samples

## However, the associations vary slightly, depending on whereabouts in Labrador the lake-sediment samples are selected from.

**Table 2:** Elements in Factor 1 association in four areas of Labrador. Elements common to all three areas are printed in red. Elements in parentheses display negative factor loadings.

Area	Elements in Factor 1 with <u>Varimax</u> - rotated loadings (Davis, 1973) greater than	Percentage of total variance accounted by
	0.5, in descending order of strength	this factor
SE Labrador	K2, Na2, Sr2, Zr2, Mg2, Hf1, Rb1, Ti2, Ba2,	37.1
	Ca2, Nb2, A12, Li2, Sc2, F9, Pb2, Cr2, Be2	
S-C Labrador	Na2, Sr2, K2, Ti2, Ba2, Mg2, Hf1, Zr2, Ca2,	38.1
	Rb1, Nb2, A12, Sc2, Li2, Pb2, F9, Cr2, Th1	
	(LOI)	
SW Labrador	K2, Ti2, Rb1, A12, Mg2, Nb2, Zr2, Na2, Hf1,	42.6
	Ba2, Sc2, F9, Be2, V2, Li2, Cr2, Th1, Sr2,	
	Pb2, Fe2, Mn2 (LOI)	
N Labrador	Na2, Sr2, K2, Ba2, Ti2, A12, Ca2, Hf1, Rb1,	33.2
	Nb2, Zr2, Mg2, Sc2, Li2 (LOI, Hg18, Br1)	

(Table from Amor, S.D., "Geochemical Quantification of the clastic component of Labrador lake sediments and applications to exploration", Government of Newfoundland and Labrador, Department of Natural Resources, Geological Survey, Open File LAB/1625, 2014.)

## **The Labrador-Québec dataset**

New analyses of old Labrador samples, using same digestion applied to Québec samples, so that data "match" on either side of border

Smoothing

# K distribution does not reflect bedrock geology

### Data have been smoothed to extract "signal" from "noise" and clarify regional picture

(from Amor, McCurdy and Garrett, "Creation of an atlas of lake-sediment geochemistry of Western Labrador and Northeastern Québec", Geochemistry: Exploration, Environment, Analysis, Volume 19, Number 1, 2019.)

The trough the trough

Some levelling was necessary, although not between Labrador and Québec data

Some examples of the distinctive geochemistry of the Labrador Trough

## The Labrador lake dataset

National Geochemical Reconnaissance samples collected and analyzed by GSC; subsequently analyzed at GSNL for additional elements

### **Distribution of Labrador lake-sediment samples**

(northern Torngats not sampled as stream drainage is better developed)

## The Newfoundland lake dataset

Analyzed by GSNL for same elements and by same methodology as NGR (AA, INAA).

The frequency distributions of several key elements in the Newfoundland lakesediment dataset are too severely truncated or censored for use in GWR (or many other statistical procedures)

## The Newfoundland till dataset

Analyzed by GSNL by INAA and multiacid/ICP-OES etc.

(considering fluoride only in this study)

### **Results** Local R<sup>2</sup> (strength of relationship)

Relationship between *partial* (aqua regia) Na and explanatory variables LOI, Rb, Sc is strong, but variable.

Relationship between total (INAA) Na and explanatory variables LOI, Rb, Sc is very strong almost everywhere

Relationship between total (INAA) Na and explanatory variables LOI and Sc is variable (no other explanatory variables available) Relationship between Cd and explanatory variables LOI, Rb, Ti changes sharply at same discontinuity defined by original analyses; demonstrates that "calibration shift" was accompanied by a deterioration of the precision.

![](_page_52_Figure_8.jpeg)

Although fluoride shows strong 48°N correlation with elements like phosphorus (suggesting the presence of fluorapatite), fluoride values are very low in tills collected over the Holyrood granite. So the minerals in which these elements are N°21 associated with fluoride are unlikely to be very abundant.

Raw K values (reminder)

![](_page_55_Figure_4.jpeg)

GWR residuals of K, Rb and Cs delineate a zone parallel to strike of Labrador Trough.

#### Residuals (Newfoundland Lake Sediments)

![](_page_57_Figure_0.jpeg)

"Predictability"

### Issues to be addressed: 1. Multiple Truncation

If it is accepted that populations in which more than 10% of the analyses are less than the detection limit are unacceptable, then <u>every</u> such population, of the many thousands (potentially) in the GWR should be excluded. ArcCIS offers no facility to do this

### Issues to be addressed:

2. "Excessive predictability"

Even the poor predictors (both theoretically and empirically) seem to be capable of recreating the observed values of certain elements; at least, on a regional scale and after the data are smoothed.

### LOI, Rb and Sc are much better predictors ...

![](_page_60_Figure_1.jpeg)

... than Fe and Mn. Which is to be expected.

LOI, Rb and Sc are good predictors of the fluoride content (which is to be expected ...)

![](_page_60_Figure_4.jpeg)

Lake Sediments Observed -of the particular

320 Kn

### "Global"

(regression equation derived for entire Labrador dataset)

![](_page_60_Figure_7.jpeg)

### 160 80 **GWR**

... but so are Fe and Mn!

![](_page_61_Picture_0.jpeg)
